SIG'NALS (*Fr.*), certain signs agreed upon between parties at a distance; for the purpose of conveying instantaneous information, orders, &c. Signals are particularly useful in the navigation of fleets, and in naval engagements. They are made by the admiral or commander-in-chief of a squadron, either in the day, or by night, whether for sailing, fighting, or the better security of the merchant ships under their convoy. They are very numerous and important, being all appointed and determined by the lords of the admiralty, and communicated in the instructions sent to the commander of every ship of the fleet, or squadron before their putting to sea.——*Day-signals* are usually made by the sails, by flags and pendants, or guns; *night-signals*, by lanterns disposed in certain figures, rockets, or the firing of guns; *fog-signals*, by guns, drums, bells, &c. There are signals of evolution addressed to a whole fleet, to a division, or to a squadron; signals of movements to particular ships; and signals of service, general or particular. The signals used in the army are usually made by beat of drum, or the sound of the bugle.——SIGNALS, on Railways, the means used to give notice of the dangerous proximity of one train to another. By day they are generally a modified form of the old telegraph with moveable arms; by night, coloured lamps, explosive balls placed on the line, &c. But no perfectly satisfactory system has yet been devised.

SIG'NATURE (*Fr.;* from *signo*, I mark with a seal: *Lat.*), the name of a person written or subscribed by himself.——In MUSIC, the flats and sharps, placed after the clef, at the beginning of the staff; they affect all the notes of the same letter, in the movement.——In Printing, a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder, in folding, gathering, and collating them.

SIGN-MAN'UAL, in English polity, the royal signature. In a general sense, it is the signature of any one's name in his own hand-writing.

SI'LEX, or **SIL'ICA** (*silex*, a flint: *Lat.*), substances in nature. It is a constituent in most rocks and stones, and common quartz, flint and agate, consist almost entirely of it. It may be obtained in a separate form by heating pure and colourless rock crystal to redness, and quenching it in water; it is then opaque and friable, and reduced to powder is nearly pure silica. It consists of one atom of silicon or silicium, and probably three atoms of oxygen; it forms salts with bases, and hence is often called silicic acid. It is found in either the soluble or insoluble form. Its specific gravity is about 2·6; it can only be fused by the oxyhydrogen blowpipe. If fused with three parts carbonate of potash it forms a soluble glass, the solution obtained from which was formerly called *liquor of flints*. [See WATER-GLASS.] But, if the proportions are reversed, that is, if three parts silex and one part carbonate of potash are used, the result will be insoluble or ordinary glass.

SIL'HOUETTE (*Fr.*), the representation of an object in a black colour, with the prominent features generally lightened, and the shadows indicated by being touched with gum.

SIL'ICATES, in Chemistry, compounds of silica, or silicic acid, with certain bases, as alumina, lime, magnesia, soda, &c., constituting the greater number by far of the hard minerals which encrust the globe.

SILI'CIUM, or **SIL'ICON**, in Chemistry, the undecomposed base of silica. It may be obtained by bringing potassium in contact with pure silex, heated to whiteness. It is dark coloured, without lustre; is probably not metallic; and bears a great analogy to boron. It is a non-conductor of electricity; it burns if heated in the air, and is converted into silica. Sulphur and chlorine also act upon it. Hydro-fluoric acid is the only acid that will dissolve it.

SIL'IQUA, or **SIL'IQUE** (*siliqua*, a pod: *Lat.*), in Botany, a long narrow seed vessel, shaped like a pod, with a membraneous division called a *replum* along the middle. When ripe it splits open by two valves from the base. When the seed vessel is broad and short it is termed a *silicula*. Seed vessels of this kind are possessed by cruciferous plants.

SILK, and **SILK'-WORM**. Silk, in its original state, is an animal fluid hardened by the air; being an extremely soft and glossy thread, spun by the *Bombyx mori*, or silk-worm. From a small egg, of the size of a pin's head, proceeds a minute dark-coloured worm, the food of which is the mulberry leaf. After casting its skin three or four times, as its bulk increases, it becomes at length a caterpillar about three inches in length, of a white colour, more or less tinctured with blue or with yellow. The period of its existence in this state being arrived, it ceases to eat, and soon begins to form the silken ball which renders it so famous. On the first day of its work, it makes the web, or loose outward silk by which it fastens its nest to the branch, paper, or other substance that nature or art puts in its way. On the second day it begins to form its *folliculus* or ball; and on the third is quite hid by its silk. At the end of ten days, the work is finished, and the transformation of the insect complete. In a state of nature everything now remains quiet till the pupa becomes a moth. Where the insect is bred as an article of trade, the ball is taken from the mulberry tree in the condition at which it is now described to be, and the silk-worm having been killed by heat, is unwound. If the animal were left to itself, it would pierce its way through, and spoil the silk. As soon as the worms have produced their balls, or cocoons, they become an article of commerce; for in those countries where silk is cultivated, few persons reel off their cocoons, but sell them to others, who make this operation a separate business. The silk, as formed by the worm, is so very fine, that if each ball, or cocoon, was reeled separately it would be totally unfit for the purpose of the manufacturer; in the reeling, therefore, the ends of several cocoons are joined and reeled together out of warm water, which, softening their natural gum, makes them stick together so as to form one strong thread.——The first silk known in Europe appears to have been brought from China. For, though a trade in silk began in a very early age, it was not before A.D. 555 that the arts of rearing the worms and working the silk were known to the western world. When silk was first introduced into Rome it was so costly that it sold for its weight in gold, and was only used by a few ladies of the patrician rank. In the beginning of the reign of Tiberius a law was passed, that no man should disgrace himself by the effeminate practice of wearing silken garments; but Heliogabalus broke this law, by wearing a dress composed wholly of silk. The example was quickly followed, and from the capital the practice soon extended to the provinces. Greece was distinguished not only for the rearing of silk-worms, but for the skill and success with which the manufacture was carried on by the inhabitants of Thebes, Corinth, &c. In time it spread to Italy; and in 1480 it was introduced into France. For a long time the English were indebted for silk to foreign nations; James I. endeavoured to introduce the breeding of the silk-worm into this country, but failed; the climate does not appear to be suited to it. But in consequence of the persecution of the Protestants in France, in the year 1685, on the revocation of the edict of Nantes, nearly 50,000 of the inhabitants fled from that country and took refuge in England; and many of them being silk manufacturers, we may trace to them the origin of the *silk trade* in Spitalfields.——As a specimen of individual enterprise in this branch of manufacture, we must notice Sir Thomas Lombe, who, about the year 1719, erected in an island on the Derwent, near Derby, a curious mill for the manufacture of silk, the model of which he had brought from Italy, at the hazard of his life. This machine was deemed so important that, at the expiration of Sir Thomas's patent, parliament voted him 14,000*l.* for the risk he had incurred, and the expense attending the completion of the machinery. It contained 26,586 wheels; one water-wheel moved the whole, and in a day and night it worked 318,504,960 yards of organzine silk thread. Such, however, have been the extraordinary improvements in the arts, that this once wonderful piece of workmanship has been disused for some years; and more efficient machinery erected, which performs twice the work. 12,077,931lbs. of raw silk were imported in 1857; upwards of 33,000 persons, in above 800 manufactories, were engaged in manufacturing it; the value of the imported article was 13,143,839*l.*; and the manufactured article was exported to the value of 2,889,829*l.* Silk changes its name as its manufacture progresses. When wound off the cocoons it is *raw silk*; when one of the reeled threads is twisted to give it strength it is *singles*; when two or more threads are twisted together, it is *tram*, and is generally used as the 'shoot,' or 'weft'; when two or more singles are twisted together, in a direction contrary to their own twist it is *thrown silk*; the process is called *organzining*, the silk thus manufactured *organzine*, and it serves for the 'web' of the best silk stuffs. The silk which the silk-worm first forms, by throwing the thread in different directions, and also that from any cause not reeled off, is *floss* (*filoselle: Fr.*), and is used for carding and spinning.

SILK-COTTON TREES; these are East Indian trees of noble aspect, which belong to the genus *Bombax*, nat. ord. *Sterculiaceæ.* They are so called from the cottony hairs which envelope the seeds. It cannot, however, be employed in manufactures, on account of the shortness of the fibre.

SILK'-THROWER, or **SILK'-THROWSTER**, one who winds, twists, spins, or throws silk, to prepare it for weaving.

SILL (*syl: Sax.*), in Architecture, the horizontal piece at the bottom of a framed case, such as a door or window.——*Ground sills*, the timbers on the ground upon which are placed the posts and superstructure of a wooden building.

SIL'LIMANITE, a greyish-brown mineral, occurring in long, slender, rhombic prisms; found in Connecticut, and named in honour of Professor Silliman. It consists of silica and alumina, with a trace of oxide of iron.

SIL'LON, in Fortification, a work raised in the middle of a ditch, to defend it when it is too wide.

SILU'RIAN SYSTEM, in Geology, a series of formations, belonging to the primary period, so named by Sir R. Murchison from having been studied by him in part of Wales and some contiguous English counties, which were once inhabited by the Silures, a tribe of ancient Britons. It has been divided into three portions, Upper, Middle, and Lower. The Upper Silurian consists of: 1. the Ludlow formation, subdivided into the Upper Ludlow rocks, the Aymestry limestone and the Lower Ludlow rocks; these have a total thickness of probably 2800 feet, and they abound with marine mollusca, especially Brachiopoda, placoid fishes, the oldest piscine remains yet discovered, trilobites, and other crustaceans. 2 The Wenlock formation, more than 2000 feet thick, divided into Wenlock limestone and Wenlock shale. The Middle Silurian rocks consist of the Caradoc formation, composed chiefly of sandstones and shelly limestone, having a total thickness of 2000 feet. The Lower Silurian rocks consist of the Llandeilo formation, composed chiefly of dark calcareous flags, with slates and sandstones, the total thickness amounting to no less than 20,000 feet, the greater part of which has accumulated as mud in a deep ocean The Silurian system has underneath it the CAMBRIAN group, and above it the DEVONIAN series.

SILU'RIDÆ, a large family of malacopterygian fishes, which includes several curious forms. Many of the species are furnished with long filamentary appendages on the head, which serve as feelers. Some small fishes belonging to this family have been expelled from active volcanoes in South America, at a height of 16,000 or 17,000 feet above the sea, a fact that has given rise to much speculation. The *Malapterurus electricus*, a fish living in the Nile and

Senegal, and possessing electrical organs, is also a member of this family. If touched on the head an electrical discharge immediately ensues, causing a pain more or less severe, accompanied by numbness. Even a fish only seven inches long will communicate a shock.

SIL'VER, a well-known precious metal, of a brilliant white colour; next to gold, the most malleable of all metals. It is very tenacious, and soft when pure; it affords leaves not more than the $\frac{1}{100000}$ of an inch thick; and wire much finer than a human hair. It is rendered harder by the addition of a small quantity of copper. Its spec. grav. is 10·5, it is not altered by air or moisture, but is blackened or tarnished by sulphuretted hydrogen. Melted in open vessels it absorbs oxygen, which it gives out in cooling; a small per centage of copper prevents this. It melts at about 1280° Fahr. The only pure acids which act on silver are the nitric and sulphuric; the former dissolves it without the aid of heat; and any gold which may have been combined with the silver remains undissolved, as a black powder. The solutions of the nitrate or sulphate are decomposed by some of the other metals, copper being most convenient for the purpose, and the silver is thrown down in the metallic state. Any solution containing a salt of silver is precipitated, or, if the quantity is small, rendered turbid by chlorine, or a soluble chloride; the insoluble chloride of silver being found, and thrown down. Silver is found in different parts of the earth; but it is in the centre of the Andes, in situations which, though exposed to the perpendicular rays of the sun, are constantly covered with snow, that nature has most abundantly distributed this metal. The silver mines of Mexico and Peru far exceed in value the whole of the European and Asiatic mines; for we are told by Humboldt that three of them, in the space of three centuries, afforded 316,023,883 pounds troy of pure silver; and he remarks that this quantity would form a solid globe of silver, 91,206 English feet in diameter. The most important silver mines of Europe at present are those of Saxony, Hungary, and the Hartz. The annual produce of these united is about 180,000*l.* Within the last quarter of a century there has been a great increase in the produce of silver from the Russian mines. The celebrated mines of Königsberg, in Norway, once so rich in native silver, are now nearly exhausted. Silver has also been obtained from some of the lead mines of Great Britain. Different methods are employed in different countries to extract silver from its ores. In Mexico, Peru, &c., the mineral is pounded, roasted, washed, then triturated with mercury in vessels filled with water; and a mill being employed to keep the whole in agitation, the silver by that means combines with the mercury. The alloy thus obtained is afterwards washed, to separate any foreign matters from it, and then strained and pressed through leather. This being done, heat is applied to drive off the mercury from the silver, which is then melted and cast into bars or ingots. Amalgamation with mercury is practised also in Europe; but it does not answer when the ore contains more than 7 pounds of lead or 1 pound of copper per cent., as the lead would render the amalgamation very impure, and the copper would be wasted. The silver ore is sometimes operated on by a saturated solution of common salt; which at a boiling temperature dissolves chloride of silver, and deposits it when cooled and diluted.

SIL'VERING, the application of silver-leaf to the surface of metals, glass, &c., or the art of covering the surfaces of bodies with a thin film of silver. Copper and brass are the metals on which the silverer most commonly operates. When silver-leaf is to be applied, the methods prescribed for gold leaf are suitable. [See GILDING.]

SIL'VER-TREE, the *Leucadendron argenteum* of botanists, nat. ord. *Proteaceæ*, is shrub growing at the Cape of Good Hope with foliage covered with a dense short pile of white hairs; whence its name.

SIMI'IDÆ (*Lat.*; from *simus*, flat-nosed in Zoology, a family of quadrumanous animals, including those belonging to the old world. The true apes, or those without tails, such as the gorilla and chimpanzee, the long-armed apes [see HYLOBATES], the capped apes of Asia, the monkeys with long tails and large cheek pouches, and the baboons [see CYNOCEPHALUS], all belong to this family.

SIM'ILE (*similis*, resembling: *Lat.*), in Rhetoric, a comparison of two things, which, though different in some respects, agree in others; by which comparison the character or qualities of a thing are illustrated or presented in an impressive light.

SIMO'NIANS, in Church History, a sect of ancient heretics; so called from their founder, Simon Magus, or the magician, who pretended to be the great virtue and power of God, sent from heaven to earth. Their system was a compound of the philosophy of Plato, the mythology of the heathens, and the doctrines of Christianity. They believed in the transmigration of souls, and denied the resurrection of the body. They are considered the first heretics in the church.

SIM'ONY (*simonie*: *Fr.*), in Law, the illegal buying or selling ecclesiastical preferment; or the corrupt presentation of any one to a benefice for money or reward. The word is derived from the *Simon Magus*, the Chaldæan, who, according to the Acts of the Apostles, wished to buy of them the power of working miracles.

SIMOON', a hot suffocating wind, that blows occasionally in Africa and Arabia, and is generated by the extreme heat of the parched deserts and sandy plains. Its approach is indicated by a redness in the air, and its fatal effects are to be avoided, only by falling on the face and holding the breath. [See SAMIEL.]

SIM'PLE CON'TRACT, in Law, a term applied to a contract which is neither ascertained by matter of record nor contained in a deed under seal.

SIMULA'TION (*simulatio*; from *simulo*, I assume the appearance of: *Lat.*), the assumption of a deceitful appearance or character. It differs from *dissimulation*, inasmuch as it assumes a false character, while dissimulation only conceals the true one; but both are justly designated by the word *hypocrisy*.

SIN'APISM (*sinapismos;* from *sinapi*, mustard: *Gr.*), in Medicine, a mustard poultice; a mixture of mustard and vinegar generally applied to the calves of the legs or soles of the feet as a stimulant, and employed in low states of fevers and other diseases.

SIN'CIPUT (*Lat.*, perhaps a contraction of *semicaput*, half the head), in Anatomy, the forepart of the head, reaching from the vertex to the eyes in mammals; and from the vertex to the base of the beak in birds.

SINE (*sinus*, a curved surface: *Lat.*), in Geometry, a right line drawn from one end of an arc perpendicular to the radius drawn to the other end.

SI'NECURE (*sine-cura*, without solicitude: *Lat.*), a church benefice without cure, or care, or guardianship of souls; as where there is a parish without church or inhabitants. The word is applied to any post that brings profit without labour.

SI'NE DI'E (without a day: *Lat.*), in Parliamentary language, a phrase applied to the adjournment of a debate when no date is named for it to be resumed.——In Law, a term applied to a defendant when judgment is given in his favour, and he is suffered to go *sine die*, or dismissed the court.

SINGING. [See MUSIC, MELODY, &c.]

SIN'ISTER (left: *Lat.*), usually signifies *unlucky*, although the Romans understood it in a different sense, a bird or thunder, on the left hand, being considered a lucky omen.——In Heraldry, a term denoting the left side of the escutcheon.——*Sinister aspect*, in Astrology, an appearance of two planets happening according to the succession of the signs; as, Saturn in the same degree as Aries, &c.

SINK'ING FUND. Alarmed by the rapid progress of the National Debt, many persons had proposed schemes for its reduction, and amongst these was the device of a sinking fund, which Dr. Price advocated in a pamphlet published in 1771. In 1786, when Mr. Pitt was Chancellor of the Exchequer, an act of parliament was passed to establish a sinking fund, the plan of which was to set aside a million annually to be invested by commissioners in the purchase of stock. The dividend of the fund so acquired was to go on accumulating for a time, with the final object of being applied in discharge of the national debt. This scheme was carried out for many years, until the commissioners had acquired upwards of 188 millions. But the time came when it was seen that the sinking fund was not only a clumsy but a costly imposture. In those times the debt was increased with fearful rapidity, for the war occasioned expenses that far exceeded the annual income. It is now clear to us that a sinking fund on such a plan is a mere chimera, unless the nation can, in addition to the sums set apart to maintain it, discharge the interest of the existing debt and pay their current expenses. Unless this can be done a new debt may accumulate with twice the rapidity that the old one can be cancelled. The only fund now applied to the cancelling of the national debt is that arising from any chance surplus of income over expenditure.

SIN'NET, or SEN'NIT (*seven knit*), in seamen's language, rope yarn bound about ropes to prevent them from galling. Also, a flat plait of rope yarns, more pliable than, but as strong as, a rope containing the same quantity of material.

SI NON OM'NES (if not all: *Lat.*), in Law, a writ on association of justices, by which, if all in commission cannot meet at the day assigned, it is allowed that two or more of them may proceed to finish the business.

SIN'TER (a scale: *Ger.*), in Mineralogy, a substance which appears under different forms, and is variously designated. *Calcareous sinter* is a variety of carbonate of lime, composed of successive layers, concentric, plane, or undulated. *Silicious sinter* is of a dull grayish white colour, and of a light, brittle, and fibrous texture. These two species of sinter are deposited by hot mineral waters when they come to the surface of the earth. *Opaline silicious sinter* is whitish, with brown, black, or blueish spots, and its fragments appear to be dendritic *Pearl sinter*, or *florite*, has a gray hue, and occurs in cylindrical, stalactitic, and globular masses.

SINTOO, or SINSYU, the original national religion of Japan, upon which Buddhism has been grafted.

SIN'UATE (*sinno*, I curve: *Lat.*), in Botany, an epithet to a leaf that has a margin that curves in and out.

SI'NUS (*Lat.*), in Anatomy, a cavity in a bone or other part, wider at the bottom than at the entrance. The veins of the dura mater are so termed.——In Surgery, a long, hollow, narrow track, leading to some abscess, in which pus is collected.

SI'PHON, or SY'PHON (*siphōn: Gr.*), in Hydraulics, a bent pipe or tube whose ends are of an unequal length; used for drawing liquor out of a vessel, by causing it to rise over the rim. The short end being inserted in the liquor, the air is exhausted by being drawn through the longer one. The pressure of the atmosphere makes the liquor rise to supply the vacuum, till it reaches the top of the vessel, and it then flows over and will continue to run till it is all exhausted. If the syphon is filled with the liquid, and the longer extremity closed until the shorter is placed in the vessel, there will be no necessity for exhausting the air; and it may be kept constantly ready for action, if the fluid is retained in it, by a cock placed in its longer end. The legs of a syphon may be equal, as its action depends on the difference between the length of the column *above* the fluid in the vessel, in one leg, and the length of the column of fluid in the other; as long as the column in the external leg is longer than the unsupported column in the internal leg, the instrument will act; and the liquid will flow with a velocity proportional to this excess of length in the external column.

SIPHO'NIA ELAS'TICA, the systematic name of the tree which produces the South American India rubber. It belongs to the nat. ord. *Euphorbiaceæ*, and it grows only on the low-lands of the Amazon region. In bark and foliage it is not unlike the ash; its trunk, however, is very tall and without branches below. The value of the India rubber annually exported from Para is about 400,000*l*. The rubber that comes to us from India and Africa is the produce of various species of *Ficus*. [See CAOUCHOUC].

SI'REN (*Lat.; from Seirēn: Gr.*), in Antiquity, a fabulous being, something like the mermaids of later times. The sirens are represented by Ovid, &c. as sea monsters, with women's faces and the tails of fish; and by others decked with plumage of various colours. The three sirens were supposed to be the three daughters of the river god Acheloüs by the muse Calliope, and were called Parthenope, Ligea, and Leucosia. Homer mentions only two sirens, and some others reckon five. Virgil places them on rocks where vessels are in danger of splitting. Some represent them as such charming monsters, who sung so harmoniously, that sailors were wrecked on their rocks without regret, and even expired in raptures.——*Siren*, a genus of Batrachian. The *Siren lacertina*, the mud-eel of North America, is shaped like an eel, saving that it has a pair of feet. It has permanent gills as well as lungs. It is allied to the Proteus.

SI'REX, in Entomology, a genus of Hymenopterous insects, of which the Sirex gigas may be considered the type. The extremity of the abdomen is prolonged into a horn.

SIRI'ASIS (*seireasis*; from *seirios*, scorching: *Gr.*), in Medicine, an inflammation of the brain, often proceeding from the intense heat of the sun. It is peculiar to children, and attended with a hollowness of the eyes and a depression of the fontanel, or space between the frontal and parietal bones.

SIR'IUS (*Lat.*; from *seirios*, literally scorching: *Gr.*), in Astronomy, the *Dog-star*, a very bright star of the first magnitude, in the mouth of the constellation of the Great Dog; it is the α Canis Majoris of astronomers. Its distance from us is calculated to be 130,000 millions of miles. This is one of the earliest named stars in the heavens, and is supposed by some to be the nearest to the earth. Hesiod and Homer mention only four or five constellations, or stars, and this is one of them. Sirius and Orion, the Hyades, Pleiades, and Arcturus, comprise almost the whole of the old poetical astronomy. The three last the Greeks formed of their own observation, as appears by the names; the two others were Egyptian. According to some, Sirius was so called from the Nile, one of the names of that river being Siris; and the Egyptians, seeing that river begin to swell at the time of a particular rising of this star, paid divine honours to it, as the star of the Nile.

SIROC'CO (*Ital.*), a periodical wind which generally prevails in Italy and Dalmatia every year, about Easter. It blows from the south-east by south, and is attended with heat, but not rain; its ordinary period is twenty days, and it usually ceases at sunset. When the sirocco does not blow in this manner, the summer is almost free from westerly winds, whirlwinds, and storms. The wind is prejudicial to plants, drying and burning up their buds; and also causes an extraordinary weakness and lassitude in men.

SIRVENTE, poems of the Provençals, the object of which was war, politics, or satire. They usually consisted, like the *chansons* or love songs, of five stanzas and an envoy.

SIS'TRUM (*seistron*, from *seis*, I shake: *Gr.*), in Antiquity, a musical instrument, of an oval shape, used by the Egyptians in the worship of Isis. It was a kind of timbrel.

SIVA, the third of the Hindoo triad of divinities, who amongst a thousand names bears also that of Mahadeva. His worshippers are spread over India, and the sects are very numerous. The greatest confusion exists as to his attributes; now he is said to be the destroyer, and now the creative principle. The chief mark of his worship is the linga, a conical black stone, which is to be seen in all his temples. He has appeared on earth in various avatars (incarnations), like Vishnu. He is represented with five faces, from four to ten hands, with a third eye in the middle of the forehead, with earrings of snakes, and a collar of skulls. As the lord of dread he is rendered as hideous as possible. In one of his characters he delights in bloody sacrifices, and with reference to this the temple of Juggernaut was built, and the notoriously cruel rites of the devotees practised. His consort Sakti was the goddess of the THUGS.

SIVATHE'RIUM (*Siva*, and *thērion*, a wild beast: *Gr.*), an extinct genus of ruminant animals, the fossil remains of which have been found in the tertiary strata of the Sivalik sub-Himalayan range. They were larger than any known ruminant, and had four horns.

SIXTH, in Music, an interval formed of six sounds, or five diatonic degrees. There are four kinds of *sixths*: two *consonant* and two *dissonant*.

SIZAR, the lowest class of students at Cambridge, &c. Sizars have usually free commons, and receive various emoluments, through the benefactions of founders and others. The name is derived from the college word *size*, the portion of bread, meat, &c., allotted to a student. [See SERVITOR.]

SIZE (*sisa: Ital.*), a glutinous substance prepared from different materials, and used by plasterers, painters, and others. It is made from the shreds and parings of leather, parchment, vellum, &c.

SIZ'EL, in Coining, the residue of bars of silver, or other metal, after the pieces are cut out for coins.

SKALDS (*Skalda*, ancient *Norsk*), ancient Scandinavian poets who lived from the tenth to the thirteenth century. 'One of the chief features of the Skaldic poetry (says Max Müller) was this, that nothing should be called by its proper name. A ship was the beast of the sea; blood, the dew of pain, or the water of the sword; a warrior was an armed tree, the tree of battle; a sword, the flame of wounds. In this poetical language there were 150 names for Odin; an island could be called by 120 synonymous titles.'

SKATE, the popular name of some cartilaginous fishes of the genus *Raia*, to which the rays also belong. What is called the *True skate* is the *Raia batis* of ichthyologists, a voracious fish which sometimes is taken of the weight of 200lbs. It is used as food.

SKEL'ETON (a dried body: from *skello*, I make dry: *Gr.*), in Anatomy, a collection of the bones of an animal cleansed, disposed in their natural situation, and kept in that order by means of wires, &c. When the bones are connected by the natural ligaments, it is called a natural skeleton; when by other means, it is termed an *artificial* skeleton.

SKEW BACK, in Architecture, the sloping abutment, in brickwork or masonry, for the ends of the arched head of an aperture.

SKEW BRIDGE. When an arch is carried across a road or stream at any angle other than a right angle, it is made askew, and its figure is derived from that of a symmetrical arch by distortion in a horizontal plane. Railway bridges are frequently skew bridges.

SKIN, in Anatomy, one of the principal integuments of the body, consisting of three layers composed of cells; namely, the *epidermis cuticle*, or scarf skin, which is the outermost; the *rete mucosum*, or second; and the *cutis vera corium*, this being the part which forms leather when tanned. There are many papillæ upon it, and in these the nerves of general sensation terminate. There is also a network of blood-vessels which forms what is called the vascular layer. The epidermis is insensible, being destitute both of nerves and blood-vessels. This is the layer of which the scales of reptiles, the nails and claws of mammals, and the hard casing of crustaceans, are modifications. The scales of fishes and the feathers of birds grow from the vascular layer *cutis vera*, or real skin, the third. On viewing the surface of the skin, even with the naked eye, we find it porous; more so in some places than others; and the pores are also larger in some parts than others. Some of these pores are ducts of sebaceous glands, and others serve not only to transmit hairs, but, it is supposed, the greatest part of the perspirable matter itself. The *rete mucosum* gives the colour to the skin; it is black in the negro [See NEGRO]; white, brown, or yellowish, in the European. The skin is extremely distensible and elastic; it is thickest on those parts which bear weight and pressure; for example, on the back, the soles of the feet, and the palms of the hands; thinner on the forepart of the body, on the insides of the arms and legs, and where two surfaces touch.——SKIN, in Commerce, the hairy or other membrane stripped off any animal to be prepared by the tanner, skinner, or parchment-maker.

SKINK (*skinkos*: *Gr.*), a scaly reptile of the lizard order, the *Scincus officinalis* of zoologists. It is from six to eight inches long, and of a yellowish colour, with black cross bands. It lives on insects and haunts sandy places in Africa, in Sicily, and some of the Greek islands. It was formerly used as a remedy in various diseases.

SKOL'IZITE (*skolios*, twisting: *Gr.*), a mineral, occurring crystallized, and massive, colourless and nearly transparent. When a small portion of it is placed in the exterior flame of a blowpipe it twists like a worm, becomes opaque, and is converted into a glassy substance.

SKOR'ODITE (*skorodon*, garlic: *Gr.*), a mineral of a greenish colour. It occurs massive, but is generally crystallized in rectangular prisms. It is an arseniate of iron; and resembles one of the arseniates of copper. When heated, it emits the odour of garlic.

SKULL, the bony covering of the brain. [See CRANIUM.]

SKUNK, the *Mephitis Americana* of zoologists, a carnivorous quadruped, about the size of a cat, and allied to the weazel and badger. It inhabits most parts of North America, and is remarkable for the intolerable stench which it emits when threatened with danger, and which is its defence against its enemies. Such, indeed, is the offensive nature of the fluid which the skunk ejects, that the smallest drop is sufficient to render clothes unwearable for a great length of time. The genus is exclusively American.

SKY'-SCRAPER, in Ships, a small triangular sail sometimes set above the royal.

SLAB, in Carpentry, an outside plank or board sawn from the sides of a tree, which is frequently of very unequal thickness.——In Masonry, a table of marble, for hearths and other purposes.

SLAM, in Chemistry, a substance frequently produced in the making of alum, by calcining it too much or too little.

SLATE (*slith*, flat: *Sax.*), a kind of stone of a blueish or grey colour, which when first dug from the quarry is of soft texture, and is easily cut or split into plates for covering the roofs of houses, paving, &c. The blue slate is very light and durable; the gray is much more lasting than tiles. The slate principally in use is brought from Wales. Some other kinds also are employed, the best of which is the Westmorland slate.——*Drawing slate, or black chalk*, has a grayish black colour; is very soft, sectile, easily broken, and adheres slightly to the tongue. It occurs in beds in primitive and transition clay slate; also in secondary formations. It is used in crayon drawing, its trace upon paper being black and regular.——*Whet slate, or Turkey hone*, is a slaty rock, containing a great proportion of quartz, in which the component particles are so very small as to be scarcely discernible.——*Mica slate* is composed of the minerals mica and quartz, the mica being generally predominant

SLATY CLEAVAGE, a structure possessed by many slate rocks, by which they are fissile into thin plates in a direction different from the planes of stratification and the planes of the joints. This structure, so long a puzzle to geologists, has at last received a satisfactory explanation at the hands of Professor Tyndall, who has shown that it is the result of great pressure applied laterally at right angles to the cleavage planes in rocks composed of fine particles.

SLAVERY (*sclaverey;* from *sklave*, a slave: *Ger.*), the establishment of a right in one man over the liberty, property, and sometimes even life of another. A state of slavery is opposed to the whole nature of man, and has always been attended with evil both to the slave and his master. The English word is simply the name of the Sclavonian race. The wars of the Frank kings and emperors filled Saracenic Spain with Sclavonic captives to such an extent that in its language, as well as in those of Europe, a natural name meaning, in its own tongue, *glorious*, became the title of servitude. Among the Romans, when a slave was set at liberty, he took the *nomen* or *prenomen* of his master, to which he added the *cognomen*, by which he had been called before he became free. The African slave-trade was commenced by the Portuguese in 1442; it was, however, of only trifling extent till the 16th century. But the importation of negroes into the West Indies and America having once begun, it gradually increased, until the vastness and importance of the traffic rivalled its cruelty and guilt. In 1787 a parliamentary committee having been formed, such a mass of evidence was collected in proof of the enormities produced by the slave-trade, that a great impression was made on the public mind. By the zealous perseverance of Messrs. Granville Sharp, Clarkson, and Wilberforce, supported as they were by Burke, Pitt, Fox, and other distinguished men in both houses of parliament, this feeling was not suffered to die away; and though the struggle continued year after year, with varied success, the friends of humanity ultimately triumphed; a bill for the total and immediate abolition of the slave trade having, in 1807, been carried in both houses by immense majorities. This great question was not, however, wholly set at rest; for though the abolition of the slave-trade was effected, the liberation of the unhappy beings already in a state of slavery was not. But by the statute 3 & 4 Will. IV. c. 73, it was enacted, that on the 1st of August, 1834, slavery was to cease throughout the British dominions, and that the then existing slaves were to become apprenticed labourers; the term of their apprenticeship partly ceasing on the 1st of August, 1838, and partly on the 1st of August, 1840; when the black and coloured population became altogether free. To attain this mighty object, the sum of 20,000,000*l.* was distributed in certain proportions and according to certain conditions to the planters, as a compensation for the loss of their slaves. The horrors of the voyage from the land of his birth to that in which the wretched negro was doomed to spend the residue of his existence can scarcely be conceived. One of the slave ships in 1829 is described as having taken in, on the coast of Africa, 336 males, and 226 females, making in all 562. She had been out seventeen days, during which she had thrown overboard fifty-five. The slaves were all enclosed under grated hatchways, between decks. The space was so low that they sat between each other's legs; and they were stowed so close together that there was no possibility of their lying down or at all changing their position by night or day. As they belonged to, and were shipped on account of, different individuals, they were all branded like sheep, with the owners' marks of different forms. These were impressed on their breasts, or on their arms, burnt with a red-hot iron! Over the hatchway stood a ferocious looking fellow, with a scourge of many-twisted thongs in his hand, who was the slave-driver of the ship; and whenever he heard the slightest noise below he shook it over them, and seemed eager to exercise it. These poor creatures were packed up and wedged together in cells, only three feet high, so that they had not more than 23 square inches for each man, and 13 inches for each woman; while the heat of these horrid places was so great, and the odour so offensive, that it was quite impossible to enter them even had there been room. Another case which may be mentioned in illustration of the subject is that of a Spanish brig, in 1840. She had originally 900 slaves on board, but during a hurricane the hatches had been battened down, and on opening them 300 were found to have died from suffocation. Again the hurricane came on; the hatches were battened down a second time, and the consequence was, that 300 more of the slaves perished from the same cause, and 100 of the remaining 300 died on the passage, to Mosambique harbour.

SLED, SLEDGE, or **SLEIGH** (*sleeg: Sax.*), a carriage or vehicle moved on runners, and much used in North America while snow is on the ground. It is drawn with great facility where the use of a wheeled carriage of any kind would be impossible; and it forms the only mode of communication in the backwoods and unreclaimed districts, where roads have not been made. It affords an easy and pleasant mode of conveyance; and the season of sleighing is one of mirth and enjoyment. As the passage of this vehicle through the track which is soon made in the snow is noiseless, the animals which draw it are decorated with bells, to give notice of their approach. In England the word *sledge* is most commonly used; in America, where it is the only vehicle seen while the snow continues, it is called a *sleigh*. In Lapland the sledges are drawn by reindeer.

SLEEP (*sleepan*, to sleep: *Sax.*), one of the most mysterious phenomena in the animal world, a state in which the body appears perfectly at rest, and external objects act on the organs of sense without exciting the usual sensations. The voluntary exertions of our mental and corporeal powers being suspended, we are unconscious of what passes around us; and are not affected by the ordinary impressions of external objects. Sleep is generally attended with a relaxation of the muscles, but the involuntary motions, as respiration and the circulation of the blood, are continued. When sleep is only partial, that is, when the brain does not fully participate in it—which is known by distinctly remembered and painful and troublesome dreams—the refreshment it produces is greatly lessened. In childhood and in perfect health we dream but little; or at least so imperfectly and so slightly that the impressions experienced are scarcely recollected. ——*Sleep of Plants*, the folding of their leaves, and drooping appearance in the night. This is more strikingly seen amongst those with pinnate leaves, such as the acacias.

SLEEP'ER, in Architecture, a piece of timber on which the ground joists of a floor are laid. The term was formerly used to indicate also the valley rafters of a roof. ——In Railway Engineering, the transverse pieces of timber or iron, to which the *chairs*, in which the rails are laid, are fixed, are called sleepers.——In Ship-building, a thick piece of timber, placed longitudinally in a ship's hold, opposite the several scarfs of the timbers, for strengthening the bows and sternframe, particularly in the Greenland ships; or a piece of long compass timber layed and bolted diagonally upon the transoms.

SLEET, in Gunnery, the part of a mortar passing from the chamber to the trunnions; so contrived as to give additional strength. ——A fall of rain and snow together in fine particles.

SLEIGH. [See SLED.]

SLEIGHT OF HAND, tricks performed by persons who, through great practice, obtain a manual dexterity which enables them to effect what is apparently out of the course of nature.

SLI'DING-RULE, a mathematical instrument, used to determine measure or quantity without compasses, by sliding the parts one by another. It is used chiefly in gauging, and for the mensuration of timber.

SLIP, a place lying with a gradual descent on the banks of a river or harbour, convenient for ship building.——In Horticulture, such portions of plants as are slipped off from the stems or branches for the purpose of being planted out as sets.

SLIT'TING-MILL, a mill where iron bars are slit into nail rods, &c.

SLOE (*sla: Sax.*), a small wild plum, the fruit of the *blackthorn*, the *Prunus spinosa* of botanists, nat. ord. *Drupaceæ*.

SLOOP, a vessel of one mast, the mainsail of which is attached to a gaff above, to a boom below, and to the mast on its foremost edge; differing from a cutter by having a fixed bowsprit and a jib-stay.——*Sloop of war*, a vessel rigged either as a ship, brig, or schooner, and usually carrying from 10 to 18 guns.

SLOPS (*slop*, a covering: *Sax.*), in seamen's language, a name given to all species of wearing apparel, bedding, &c., which are supplied to royal ships in commission.

SLOTH (*slæwth: Sax.*), or AI, the *Bradypus torquatus* of zoologists, an herbivorous edentate quadruped of South America, proverbial for the slowness of its motions; but it climbs more easily than it walks, and seems quite at home when resting suspended on the branches of trees. The fore-feet or arms are much longer than the hinder and when the sloth is on the ground it is obliged to draw itself along upon its elbows.

SLOUGH (*slog: Sax.*), in Surgery, the dead part which separates from the living in mortification; or the part that comes away from a foul sore; hence the term *to slough off*. Also (with the same pronunciation), the skin or cast skin of a serpent.——*Slough* (pron. *slou*), a place or hole full of deep mud or mire.

SLOW'-WORM. [See BLINDWORM.]

SLUG, the popular name of snails with small or rudimentary shells, well known as pests in gardens. They form the genus *Limax*, and some allied genera amongst gasteropod molluscs. Also, a cylindrical cubical, or irregularly shaped piece of metal shot from a gun.

SLUICE (*escluse: Fr.*), the stream of water issuing through a flood-gate. The word is, however, used indiscriminately either for the stream that passes through the flood-gate, or the gate itself.

SLUR, in Music, a mark connecting notes that are to be sung to the same syllable, or made in one continued breath of a wind instrument, or with one stroke of a stringed instrument.

SMALL-POX, in Medicine, a very contagious pustular disease. It is found in two forms: the distinct and the confluent. *Distinct small-pox*, in which the pustules are separate, begins with pains in the back and loins, drowsiness, headache, and the other symptoms of *inflammatory* fever. The spots are first red and small, then become little vesicles, and about the eleventh day attain their full size, that of a pea; the throat after some days becomes sore, and the face swollen; the swelling of the face is then transferred to the feet and hands; the pustules ultimately break, and if they were large, leave an indentation; the remaining symptoms gradually subside, and the secondary fever disappears about the seventeenth or eighteenth day. *Confluent small-pox*, in which the pustules coalesce, is ushered in by a fever of a *typhoid* character; the symptoms are aggravated; the eruption proceeds very irregularly; the fever does not, as in the distinct kind, cease on the appearance of the eruption, but, on the contrary, are aggravated; the eruption becomes livid, and purple spots are perceived; about the eleventh day it often terminates fatally. Small-pox is the effect of a specific contagion, produced either by innoculation or exposure to the effluvia from persons suffering under it. [See VACCINATION.]

SMALTS, or SMALT (*schmalz: Ger.*), a beautiful blue colour obtained by fusing together glass and oxide of cobalt; it is used in paper-making and various other arts, particularly in the painting of earthenware. The inferior kinds are made by fusing mixtures of zaffre, sand, and pearlash.

SMAR'AGD (*smaragdos: Gr.*), another name for the *emerald*. Hence, *smaragdine*, an epithet for anything pertaining to or resembling an emerald; of an emerald green. The ancients used the word in a far more extended sense. Thus Nero is said to have viewed the combats of the Gladiators in a *smaragd*, which is supposed to mean a polished mirror.

SMARAG'DITE (*smaragdos*, the emerald: *Gr.*), in Mineralogy, a variety of *hornblende*.

SMELT, a marine fish of delicate flavour, the *Osmerus eperlanus* of ichthyologists. It is allied to the salmon, and is usually taken of the length of six or seven inches.

SMEL'LING, that sense which resides in the nerves distributed over the membrane that lines the interior of the nostrils. It is far more strongly developed in some animals than in others. Volatile particles chiefly are distinguished by smell, and fixed ones by the taste.

SMELT'ING (*smelter*, to melt ore: *Belg.*), in Metallurgy, the exposure of metallic ores to heat in order to melt out the metallic from the earthy, stony, and other parts. The art of fusing the ores, after roasting, is the principal and most important of metallurgic operations.

SMI'LAX (*Gr.*), in Botany, a genus of plants, nat. ord. *Smilaceæ*. Most of the species are climbing shrubs. The sarsaparilla of the Materia Medica is the root of some South American species.

SMOKE, the visible vapour or exhalation that is expelled from a substance while burning; or the rarefied, but undecomposed part of a combustible. The smoke emitted by fuel may be considered as so much waste of its most valuable portions. A scientific application of the principles on which combustion depends is quite sufficient to prevent the production of smoke. The word *smoke* is particularly applied to the volatile vapour expelled from coal, wood, vegetable matter, &c.; that which exhales from metallic substances being more generally called *fume*.

SMOKE-JACK, a machine consisting of an arrangement of wheels put in motion by the draught of the chimney with force sufficient to turn a vane.

SMUT (*smitta: Sax.*), in Husbandry, a disease in corn, when the grains, instead of being filled with flour, contain foul black powder. This is produced by a minute fungus called *Uredo segetum* by botanists.

SNAIL, the name given to Gasteropod molluscs, belonging to the genus *Helix*. The number of species is astonishingly great, almost every country having some peculiar to it, whilst several species have a large geographical range. The animal carries four tentacles on its head, all retractile at pleasure. The upper two have eyes at their summits. They are able to draw themselves entirely into their shells, which vary considerably in form and sculpture. Snails are very tenacious of life; Dr. Baird mentions an instance of a specimen from Egypt, having been glued down by its shell to a tablet in the British Museum for four years before it was discovered to be alive. The common garden snail, *Helix aspersa*, may be taken as an example.

SNAKE, the common and general name of serpents; but, in England, generally applied to those which are oviparous. [See SERPENTS.]

SNA'KEROOT, the *Aristolochia serpentaria*, a species of *birth-wort*, growing in North America. Its medicinal virtues are considerable, and its general action is heating and stimulant.

SNA'KEWEED, a plant of the genus *Polygonum: bistort*.

SNA'KEWOOD, the smaller branches of the *Strychnos colubrina*, a tree growing in the isle of Timor and other parts of the East; having a bitter taste, and supposed to be a certain remedy for the bite of the hooded serpent.

SNATCH'BLOCK (*snacken*, to seize hastily: *Dut.*), in ships, a great block or pulley, having a shiver cut through one of its cheeks, for the ready receiving of any rope. It is chiefly used for heavy purchases, where a warp or hawser is brought to the capstan.

SNEE'ZING, a convulsive action of the organs of respiration, produced by irritation of the nostrils. Violent fits of sneezing have been known to prove fatal; in severe cases, the nasal membrane should be soothed by applying warm milk and water, or a decoction of poppies.

SNIPE, the name of some British grallatorial birds, belonging to the genus *Scolopax*, of which the common snipe (*S. gallinago*) and the Jack snipe (*S. gallinula*) are the best known. They haunt marshy tracts and are much sought after by sportsmen.

SNOW (*snaw: Sax.*), in Meteorology, a congelation of vapour produced in the middle region of the air, when the temperature of the atmosphere sinks below the freezing point of water. The manner in which snow is produced is not well understood. It has not been ascertained whether the clouds which give rise to it are composed of vesicular vapours, or frozen particles; nor whether the flakes are completely or only partially formed before it begins to descend; nor is it known what temperatures or circumstances give rise to its different appearance. Upon examining snow flakes they are found, with rare exceptions, to be masses of beautifully formed crystals. Their variety is endless, but the principal forms are stars of six points, from one-third to one-thirty-fifth of an inch in diameter.——*Red snow*. It was observed, even by the ancients, that snow is sometimes of a red colour. This is now known to be due to the presence of a minute fungus named *Protococcus nivalis* by botanists. It has been found in many parts of the world.

SNOW, LIMIT OF PERPETUAL, a term of physical geography, referring to an imaginary line on the earth where the temperature is never below 32° F. This limit cannot be defined in a given region with strict accuracy, and all statements regard ing it can be approximate only. It is best determined where the accumulations are continuous upwards on gentle slopes. Accumulations in hollows and descending glaciers are very frequently below the limit, and hence the line is often laid down too low in mountainous regions. On the other hand, steep surfaces exposed to the sun or to moist winds are frequently destitute of snow, although above the limit in question. In the northern hemisphere the snow line sinks to the level of the sea about the parallel of 80°, and at the equator it is upwards of 16,000 feet above the sea. It is much higher on the northern slopes of the Himalayas than on the southern. This is occasioned by the fact that the rainwinds all come from the south, and that the greater part of their moisture is deposited before they arrive at the north side of the range where the air is very dry.

SNUFF, pulverized tobacco, variously prepared, scented, and distinguished by a multitude of names. It is so frequently adulterated with deleterious substances that mischievous consequences must necessarily arise from its use, in addition to those which naturally flow from employment of a narcotic powder in this way.

SOAP (*sapōn: Gr.*), a substance obtained by the action of alkalies on oils or fats. *White soaps* are generally manufactured from oil of olives and carbonate of soda, the latter being rendered caustic by quicklime, and its solution being termed *soap ley*. The oil and alkaline liquid are boiled together, until the soap begins to separate from the water, salt being sometimes added to promote granulation; the whole is allowed to rest for some time; the soap is then transferred into wooden frames, and when stiff enough is cut into oblong slices and dried. Perfumes are sometimes added; and marbling, when desirable, is effected by stirring into the soap during manufacture a solution of sulphate of iron, which is decomposed, black oxide separating in streaks and patches. *Common soap* is made of soda and tallow; or if potash is used, common salt is added to harden it by transference of soda. *Soft soaps* are generally made with potash and fish oil. *Yellow soap* contains resin. Soap is soluble in pure water and in alcohol: the solution in the latter gelatinizes when concentrated, forming what is called in medicine *opodeldoc*. If the soap solution is carefully evaporated, *transparent soap* is obtained. Earth and common metallic oxides form *insoluble soaps*: and hence soap is wasted, and precipitates are formed with it, by hard water—that is, such as contains lime. Soap, if kept in a damp place, is capable of remaining combined with a large quantity of water; this adds to its weight, and diminishes its utility, by rendering it liable to waste during use.

SOAP'STONE, in Mineralogy, *Steatite*, a soft mineral of a soapy feel. It is a hydrated silicate of magnesia and alumina.

SOAP'WORT a plant of the genus *Saponaria*: nat. ord. *Caryophyllaceæ*.

SOC'AGE (*soke*, a plough: *Ang. Sax.*), in Law, a tenure of lands by any certain and determinate services. In *free socage* the services were, in a feudal sense, not dishonourable, as the payment of an annual rent. In *villein socage*, lands were held by villein services; and these being certain and determined, the tenure was, in some respects, copyhold, and it still subsists.

SO'CIALISM (*socialis*, pertaining to companionship: *Lat.*), the science of reconstructing society on entirely new bases, or the substitution of the principle of co-operation for that of competition, in every branch of human industry. This view of society is not of recent date. It has been the favourite theme of poets from the earliest ages. But the first attempt to carry it into practical effect was made by the Saint Simonians in France about 1820, who gained numerous adherents, especially in Paris. After the revolution of July 1830, it rose rapidly into notoriety, from the sympathy between the notions which it promulgated, and those entertained by many of the republican party. The views of the St. Simonians were all directed to the abolition of rank and property in society, and the establishment of associations such as the followers of Mr. Owen in this country have denominated co-operative, of which all the members should work in common, and divide the fruits of their labour; and with these notions, common to many other social reformers, they united the doctrine that the division of the goods of the community should be in due proportion to the merit or capacity of the recipient. But their doctrines and proceedings soon became licentious and immoral; and in 1832, their association was dispersed by Government. Some former members of this body attained to places of rank and consideration; and others founded new schools of socialism and communism.

SOCI'ETY (*societas*; from *socio*, I associate: *Lat.*), in its usually restricted sense, an association organized for the promotion of some object. If formed for commercial purposes, it is usually called a *Company*. Literary societies are often termed *Academies*; societies for social purposes *Clubs*, sometimes political, and sometimes devoted to certain classes. There are about forty clubs in London, the number of members varying from 1000 to 1500, admitted by ballot; paying from ten to twenty-five guineas on admission, and from five to ten guineas annual subscription. Benevolent associations in this country are very numerous.

SOCK (*soccus*: *Lat.*), the low-heeled light shoe of the ancient actors in comedy. Hence the word is used for comedy, and opposed to *buskin* or tragedy.

SOC'LE (*zoccoli*, a shoe: *Ital.*), in Architecture, a square member, having a greater breadth than height. It is used to support a column, base, &c., instead of a pedestal, from which it differs, by having neither base nor cornice.

SOCRATIC PHILOSOPHY, in its proper signification, the peculiar method which was applied by Socrates to philosophical inquiry. His object was to stimulate his hearers to the pursuit of the good and the true by new and more comprehensive methods. He began his discourses by propositions generally received as true; and placed a particular idea in a number of combinations. He then proceeded by means of questions to ascertain the ideas of those with whom he was contending. So full of error were the speculations of his age that it was not difficult to entangle his opponent in contradictions, or to extract from him admissions which were inconsistent with his opinions, or agreeable to the sentiments of Socrates, who with his comprehensive views and dialectic ability, soon turned them to account. Socrates wrote nothing himself; we have only the reports of Xenophon and Plato, and the latter is thought to have added much of his own.

SO'DA, an alkali, the oxide of the metal *sodium*, obtained, usually as a carbonate, from several sources. It is sometimes found in a native state, as in the lakes in Egypt, which, being dried by the heat of the sun, leave beds of soda, or natron, as it is there called. Soda was formerly procured as *Barilla*, from the incinerated ashes of the *salsola* plant, and as *kelp* by burning seaweed; but it is now almost entirely obtained by decomposing common salt with sulphuric acid or iron pyrites. The resulting sulphate is fused in a furnace with chalk and small coal, and the carbonate of soda is then dissolved out of the product.——*Caustic Soda* is the oxide, and is obtained from the carbonate by boiling it with lime. Soda, in one form or other, has an immense number of applications in the arts.

SO'DALITE, a mineral of a bluish green colour, found crystallized, or in masses. It obtains its name from the large portion of soda which enters into its composition. It consists chiefly of silex, alumina, and soda.

SO'DA-WATER, a supersaturated solution of carbonic acid in water. It derives its name from having been always formerly, and sometimes at present, prepared by the addition of some carbonate of soda, to render it useful in certain forms of dyspepsia. Some ingenious machines are employed in the manufacture of soda-water.

SO'DIUM, the metallic base of soda, is obtained by raising a mixture of the carbonate and charcoal to a high temperature. It is white, opaque, and has the lustre and general appearance of silver. Its spec. grav. is 0·97; it fuses at 194°. It is exceedingly malleable, and is much softer than any of the common metallic substances. It conducts electricity and heat in a similar manner to the basis of potassa, which it very much resembles; and small particles of it inflame by the galvanic spark, and burn with bright explosions. When sodium is exposed to the atmosphere it immediately tarnishes, and by degrees becomes covered with a white crust, which is the oxide. Sodium combines with the metals; in the quantity of one-fortieth it renders mercury a fixed solid of the colour of silver, and the combination is attended with a considerable degree of heat. It forms an alloy with tin, without changing its colour; and it acts upon gold and lead when heated. Placed upon cold water it decomposes the liquid with violence; with hot water it inflames.

SOF'FIT (*soffitta*, overlaid: *Ital.*), the ceiling of subordinate parts of buildings, such as staircases, entablatures, archways, cornices, &c.

SOFI (probably a corruption of *sophos*, wise: *Gr.*), a Persian word, signifying religious persons, called also *Dervishes*. It was the surname of the kings of Persia, of the race preceding the present family, and came to be erroneously used as a title of the Persian monarch.

SOIL, the earthy materials in which plants grow; consisting of compounds of silica, lime, alumina, magnesia, oxide of iron, and various acid and alkaline combinations; with the remains of animal and vegetable matter; the variety being necessary to healthy vegetation. The part beneath that where plants usually grow is termed the *subsoil*. All soils were originally the product of disintegrated rocks—on whose nature and constitution they depend for their peculiar qualities.

SOKE (a plough: *Ang. Sax.*), in Law, a term which anciently had various significations, viz. 1. The liberty or privilege of tenants excused from customary burdens and impositions. 2. The power of administering justice. 3. The precinct in which the chief lord exercised his *soc*, or liberty of keeping court within his own jurisdiction. 4. A stipulated payment or rent to the lord for using his land, with such liberty and privilege as made the tenant the soke man or freeholder. As a territorial division it still exists in Lincolnshire.——SOKE-MEN, tenants of sokage lands: those who held by no servile tenure, but paid their rent as a soke, or sign of freedom.——SOKE-REEVE, the rent collector in the lord's soke.

SOLANA'CEÆ, a natural order of plants, including more than a thousand species. The flowers are monopetalous and regular; the fruit either a capsule or a berry. They are found in most parts of the world, some affording food, others medicines. Many of them possess narcotic properties to such an extent as to be poisonous. The genus *Solanum* has upwards of 900 species, and one of these is the valuable POTATO, and another the poisonous *Bitter sweet*. To other genera belong the TOBACCO plant (*Nicotiana*), the TOMATO (*Lycopersicum*), the Cape gooseberry (*Physalis*), the Red Peppers (*Capsicum*), the HENBANE (*Hyoscyamus*), the Thorn Apple (*Datura*), the Night Shade (*Atropa*), the MANDRAKE, and the handsome Petunia.

SO'LAN-GOOSE. [See GANNET.]

SOLA'RIUM (*Lat.*, from *solaris*, pertaining to the sun), in Antiquity, a place on the tops of houses exposed to the sun, where the Romans used to take air and exercise.

SO'LAR SYSTEM, that system of astronomy which is founded on the hypothesis that the sun is the centre of the universe, round which all the planets revolve at different distances, and in different spaces of time. [See ASTRONOMY, EARTH, SUN, PLANETS, MOON, &c.]

SO'LDAN (corrupted from *Sultan*), a title formerly given to a general who commanded the caliph's army; the epithet was afterwards applied to a governor of Egypt.

SOL'DERING (*solido*, I make firm: *Lat.*), among Mechanics, the uniting together two pieces of metal, by the fusion and application of some metallic composition on the extremities of the metals to be joined. Common solder is an alloy composed of about two parts of lead and one of tin. In the operation of soldering, the surfaces of the metal intended to be joined are scraped and rendered very clean; they are then brought close to each other. Some resin, chloride of zinc, borax, or other suitable substance having been previously placed on the places to be joined; and heat is applied by a soldering iron, or in some other way.——SOLDERS are made of gold, silver, copper, tin, bismuth, and lead; usually, but not always, in the composition some of the metal that is to be soldered being included.

SOLE, the name given to flat fishes of the genus *Solea*. The common sole abounds on the British coast; afford considerable employment to the fishermen, and are much esteemed as an article of food.

SOL'ECISM (*soloikismos*: *Gr.*), in Grammar, incongruity of language, or a gross deviation from the rules of grammar, or construction. According to Pliny it differs from a *Barbarism*, in not being confined to the use of single words, which are erroneous.——In a general sense, any unfitness or impropriety.

SOLENA'CEANS (*sōlēn*, a tube: *Gr*), a family of dimiary bivalve molluscs, of which the genus *Solen*, comprising the razor shell, is the type.

SOLFATA'RA, a volcanic vent which emits only sulphur, and its compounds; and so named from the *Solfatara*, a hill near Naples, in the district called by the ancients the *Phlægræi Campi*.

SOLI'CITOR (*solicito*, I persuade: *Lat.*), in Law, a person authorized and employed to prosecute the suits of others in the Court of Chancery; similar practitioners are called *attorneys*, in courts of common law. In Scotland solicitors are the same as attorneys with us; but they practise in the inferior courts and are inferior to *writers to the signet*.——SOLICITOR-GENERAL, an officer of the crown, holding by patent, ranking next to the attorney-general. Like the attorney-general, he resigns office when the ministry which appointed him retires.

SOL'ID (*solidus*, firm: *Lat.*), in Philosophy, a body whose parts are so connected together as not to give way or slip from each other upon the smallest impression, in which sense *Solid* stands opposite to *Fluid*.——Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, *viz.* length, breadth, thickness or depth.—*Solids* are commonly divided into *regular* and *irregular*. The *regular* solids are those terminated by regular and equal planes, and are only five in number, *viz.* the Tetrahedron, which consists of four equal triangles; the Cube, or Hexahedron, of six equal squares; the Octahedron, of eight equal triangles; the Dodecahedron, of twelve; and the Icosahedron, of twenty equal triangles. The *irregular* solids are almost infinite, comprehending all such as do not come under the definition of regular solids; as the sphere, cylinder, cone, parallelogram, prism, parallelopiped, &c.——In anatomy and medical science, the bones, flesh, and vessels of animal bodies are called *solids*, in distinction from the blood, chyle, and other fluids.——*Solid Angle*, one made by the meeting, in one point, of more than two plane angles which are not in the same plane. *Solid square*, in military language, a body of troops formed into a square, consisting of a number of parallel squares one within the other. The faces of the men in each set of parallel sides look the same way, and towards the outside of the square, holding their bayonets so as to be prepared for the attack of an enemy attempting to force the square. The solid square has been found capable of resisting even a furious charge of cavalry.

SOLIDA'GO (*solido*, I make firm: *Lat.*, from its supposed efficacy in healing wounds), in Botany, a genus of plants, nat. ord. *Compositæ*. Plants of this genus are distinguished by the name of the golden rod, on account of their yellow flowers and long spikes.

SOLIFID'IAN (*solus*, alone; and *fides*, faith: *Lat.*), in Theology, one who maintains that faith alone, without works, is necessary to justification.

SO'LO (*Ital.*), in Music, a passage, or perfect piece in which a single voice or instrument performs without accompaniment. Peculiar freedom, ease, distinctness, and power of execution, are required to perform the solo with correctness, taste, and feeling.

SOLOMON'S SEAL, the common name of a species of *Polygonatum*, belonging to the nat. ord. *Liliaceæ*. It is perennial.

SOL'STICE (*solstitium*; from *Sol*, the sun: and *sisto*, I cause to stand: *Lat.*), in Astronomy, the time when the sun is in one of the solstitial points; that is, when it is at the greatest distance from the equator, which is 23½ degrees, and when, to the people of the higher latitudes, it appears to stand still, not changing its place in the degrees of the zodiac. The solstitial points in an artificial globe are those in which the ecliptic, or path of the sun, touches the tropics.——*Summer solstice*, the 21st of June, when the sun enters the tropic of Cancer, in its progress southward, and gives the longest day. *Winter solstice*, the 21st of December, when the sun enters the tropic of Capricorn, in its progress northward, and gives the shortest day.

SOLU'TION (*solutio*, a dissolving: *Lat.*), the intimate mixture or perfect union of solid bodies with fluids, so as to form one homogeneous liquor. The word is applied both to the *act* of combination and to the *result* of the process: thus common salt disappears in water, that is, its solution takes place, and the liquid obtained is called a *solution* of salt in water.——In Algebra and Geometry, *solution* signifies the answering of a question, or the resolving of a problem.——In Surgery, the term *solution of continuity* denotes the separation of connected substances or parts applied to a fraction, laceration, &c.

SOLV'ENT (*solvens*, dissolving : *Lat.*), in Chemistry, any liquid which will dissolve substances.

SO'MATIST (*sōma*, a body : *Gr.*), one who denies the existence, and consequently the agency, of spiritual substances.

SOMATOL'OGY (*sōma*, a body ; and *logos*, a discourse : *Gr.*), the doctrine of bodies or material substances.

SOM'MITE, in Mineralogy, *nepheline ;* a mineral which occurs in small crystals. It is found on Somma and Vesuvius.

SOMNAM'BULISM (*somnium*, a dream ; and *ambulo*, I walk : *Lat.*), the phenomenon of sleep-walking, during which the sensitive and willing powers govern the muscles, while the reasoning or reflecting organs are asleep ; but in dreaming it is the contrary. The phenomena attendant on sleep-walking are very singular, the person affected performing many voluntary actions, implying a certain degree of perception of external objects. There are a number of very remarkable cases of somnambulism on record, some of which would be incredible were they not attested by unquestionable authority. Somnambulists have been known to undress and take a cold bath ; to saddle and bridle their horses, and afterwards ride to a considerable distance ; and, when their habits perhaps were more sedentary, to write letters, make verses, &c. ; while in most cases they quietly returned to their beds, and awoke at their usual hour utterly unconscious of their previous proceedings. Generally speaking, but not always, somnambulists are incapable of holding a conversation. Somnambulism may be described as a state in which the mind retains its power over the limbs, but possesses no influence over its own thoughts, and scarcely any over the body, excepting those particular members of it which are employed in walking.

SONA'TA (*Ital.*), in Music, a piece or composition wholly executed by instruments ; and generally supposed to exhibit the composer's powers without confining him within the rigid rules of counterpoint or measure.

SON'NET (*Fr.*), a short poem, which, according to its Italian model, consists of fourteen lines ; divided into two parts, the first of eight, and the latter of six lines. According to the strictest rules, only two rhymes are allowed in the first part, and the second ought not to end in a couplet ; but in our language, which possesses a comparative paucity of rhymes, the sonnet has been written with great latitude as to rhymes.

SONOM'ETER (*sonus*, a sound : *Lat.* ; and *metron*, a measure ; *Gr.*), an instrument for measuring sounds or the intervals of sounds.

SOOTH'SAYING (*soth*, truth : *Sax.*), the foretelling of future events without divine aid or authority ; and thus distinguished from *prophecy* by inspiration.

SO'PHI. [See SOFI.]

SOPH'ISM (*sophisma*, from *sophizo*, I deal subtilely : *Gr.*), a subtilty in reasoning, in which the arguments are not logically supported, or the inferences are not justly deduced from the premises.

SOPHISTICA'TION (*sophizo*, I deceive : *Gr.*), the adulterating or debasing the purity of something by a foreign admixture.

SOPH'ISTS (*sophistēs*, from *sophizo*, I deal subtilely : *Gr.*), a name at first given to philosophers and those who were remarkable for their wisdom ; it was afterwards applied to rhetoricians, and lastly to such as spent their time in verbal niceties, logical conundrums, sententious quibbles, and philosophical enigmas. The following, called the *Pseudomenos*, for example, was a famous problem amongst the ancient *sophists :* 'When a man says, *I lie*, does he *lie*, or does he *not lie?* If he lies, he speaks truth ; and if he speaks the truth, he lies.'

SOPORIF'IC (*sopor*, a heavy sleep ; and *facio*, I make : *Lat.*), in Medicine, any drug, plant, &c. that has the quality of inducing sleep.

SOPRA'NO (*Ital.*, from *sopra*, above), in Music, one of the intermediate portions of the scale, which is a species of treble, suited to the female voice.

SOR'BIC ACID, in Chemistry, acid procured from the fruit of the *Pyrus*, or *Sorbus aucuparia*, or Mountain Ash. It is identical with *malic acid*.

SORBONNE, the name of a college originally instituted for the education of secular clergymen at the university of Paris, so called after Robert of Sorbon, in Champagne, a theologian of Paris, who founded it during the reign of St. Louis, about 1250, and endowed it with an income which was subsequently much increased. This institution, the teachers in which were always doctors and professors of theology, acquired so much fame that its name was extended to the whole theological faculty of the university of Paris.

SOR'CERY (*sorcerie*, from *sors*, a lot : *Lat.*), Magic, or divination by the supposed assistance of evil spirits, or the power of commanding evil spirits.

SORD'AWALITE, a black or grayish green mineral, so named from Sordawald, in Wibourg. It is a species of hornblende and consists of alumina, iron magnesia, and a small quantity of phosphoric acid.

SOR'DES (*Lat.*), in Medicine, foul matter. Also, dregs of any kind.

SOR'EL, a term used by sportsmen for a male fallow deer of three years old.

SOR'EX (a mouse : *Lat.*), in Zoology, a genus of nocturnal insectivorous mammals, typified by the shrew mouse, which resembles the mole in the head, and the mouse in other parts.

SORGHO (*Holcus saccharatus*), a plant allied to millet, which is extensively cultivated in China, and of late years in Europe. The stem yields a juice from which sugar and spirit are obtainable, the leaves afford excellent fodder for cattle, and the seeds are suitable for feeding poultry.

SORI'TES (*sōreitēs*, from *sōros*, a heap :

Gr.), in Logic, an abridged form of stating a series of syllogisms consisting of a number of propositions so linked together that the predicate of one becomes continually the subject of the next in succession, till a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last.

SOR'REL, a name given to several plants. The common sorrel is the *Rumex acetosa*, a British herb with an acid taste. The word sorrel is the *Oxalis acetosella*. The wood-sorrel is of the genus *Oxalis*. The Indian red and Indian white sorrels are of the genus *Hibiscus*. *Salt of Sorrel*, binoxalate of potash.

SO'RTES HOME'RICÆ, VIRGILIANÆ, SANCTORUM (Homeric, &c. lots: *Lat.*), a species of divination very common in antiquity. It consisted in opening a favourite author at random, and deducing an oracular meaning from the first passage which met the eye. The Greeks used Homer for this purpose, the Romans Virgil, the Christians the Bible. Some remarkable examples are on record of the applicability of the passages found to the destinies of the finders.

SORTIE' (*Fr.*), in Military language, the issuing of a body of troops from a besieged place to attack the besiegers; a *sally*.

SOSTENU'TO (sustained: *Ital.*), in Music, a term used to denote the unbroken continuance of sounds.

SOUND, in Physics, the effect produced on the ear, usually by a tremulous motion of the air, caused by the vibration of some other body which has been struck, rubbed, &c. The distance to which sounds may be heard will be proportional to the magnitude or intensity of the stroke made on the tremulous body emitting the sound; for the greater that stroke is the greater will be the agitation of its parts, and the greater will be the force with which they will strike the particles of air. Hence the greater will be the effect at any given distance on the drum of the ear; and, consequently, the greater will be the distance at which the agitation of the air will be sensible. It is ascertained that sound of all kinds travels at the rate of 1124½ feet per second, when the air is at the temperature of 32°; the softest whisper moves as fast as the loudest thunder. The knowledge of this fact has been applied to the measurement of distances. Thus, if we see a vivid flash of lightning, and in two seconds hear a clap of thunder, we may be assured that the lightning occurred at not more than the distance of 750 yards. If the vibrations of a sonorous body fall short of or exceed a certain velocity, no sound will be perceived; the smallest number which produce any effect on the ear is 32 per second; and the largest, according to some, 8200, but according to others, 24,000 per second. Taking the velocity of sound in the air as unity, its velocity in tin will be represented by 7½, in silver by 9, in copper by 12, in iron by 17, in glass by 17, in baked clay by 10 12, and in wood by 11·17. Its velocity in cast iron was found to be only 10·5. Solids are much better conductors of sound than atmospheric air; a person at one end of a long fir beam will distinctly hear a very slight tap, which is inaudible to him who makes it at the other end. Water is a very excellent conductor of sound, particularly when frozen. Sounds have been conveyed even by land to enormous distances; the cannonade of a sea fight between the English and Dutch, in 1672, was heard across England to the extent of 200 miles.——*Sound*, in Geography, any great inlet of the sea; as Plymouth sound, &c.

SOUND'ING (*sonder*, to search with a plummet: *Fr.*), in Navigation, the operation of trying the depth of the water, and the quality of the bottom, by a line with a plummet at the end.——*Soundings*, a name given to the specimen of the ground, obtained by sounding. A piece of tallow stuck upon the base of the deep-sea lead brings up distinguishing marks from the bottom, as sand, shells, &c., which adhere to it. Their nature is carefully marked in the log-book. A ship is said to be *in soundings* when she gets into water shallow enough to be sounded.

SOUTH (*suth: Sax.*), one of the cardinal points. Strictly, *south* is the horizontal point in the meridian of a place, on the right hand of a person standing with his face towards the east. But the word is applied to any point in the meridian, between the horizon and the zenith.

SOUTHCOT'TIANS, the followers of *Joanna Southcott*. She was born in Devonshire in 1750; claimed the power of prophecying, and had many followers. In her 65th year she pretended to be supernaturally pregnant. She died soon afterwards, and although it was proved that her assertion was false, the faith of many of her followers was not shaken, and they expected her to reappear.

SOUTH'ERNWOOD, the *Artemisia abrotanum* of botanists, nat. ord. *Compositæ*, a plant with sweet-scented leaves, a native of the South of Europe, common in English gardens.

SOUTH SEA BUBBLE, a term given to a commercial 'scheme,' in 1720, which, for a time, produced a kind of national delirium in England. A company for trading to the South Seas, which was entitled the 'South Sea Company,' had been sanctioned by government, with the specious pretence of discharging the national debt, by reducing all the funds into one. Blunt, the projector, had taken the hint of his plan from Law's celebrated Mississippi scheme, which, in the preceding year, had, in France, entailed ruin upon many thousand families of that kingdom. In the project of Law there was something substantial. It promised an exclusive trade to Louisiana; though the design was defeated by the frantic eagerness of the people. But the South Sea scheme was buoyed up by nothing but the folly and rapaciousness of individuals, which became so blind and extravagant, that Blunt was able to impose upon the whole nation, and make tools of the other directors, to serve his own purpose and that of a few associates. When the projector found that the South Sea stock did not rise according to his expectation he circulated a report that Gibraltar and Port Mahon would be exchanged for some places in Peru; by which means the English trade to the South Sea would be protected and enlarged. This rumour, diffused by emissaries, acted like a contagion. In five days the directors opened their books for a subscription of 1,000,000*l.* at the rate of 300*l.* for every 100*l.* capital. Persons of all ranks crowded to the house in such a manner that the first subscription exceeded 2,000,000*l.* of original stock. In a few days this stock advanced to 340*l.*; and the subscriptions were sold for double the price of the first payment. In a little time the stock reached 1000*l.*, and the whole nation was infected with the spirit of stock-jobbing to an incredible extent. The infatuation prevailed till the 8th of September, when the stock began to fall, and some of the adventurers awoke from their delirium. On the 29th of the same month the stock had sunk to 150*l.*; several eminent goldsmiths and bankers, who had lent great sums upon it, were obliged to stop payment and abscond; and the ebb of this portentous tide was so violent that it carried everything in its way, and an infinite number of families were overwhelmed with ruin. Public credit sustained a terrible shock; the nation was thrown into a ferment; and nothing was heard but the ravings of grief, disappointment, and despair. Some principal members of the ministry were deeply concerned in these fraudulent transactions; and though they used all their influence with the Bank to assist them in supporting the credit of the South Sea Company, and actually obtained from that corporation a large sum, the bubble burst; and a committee of the House of Commons, to whom the subject had been referred, declared they had discovered a train of the deepest 'villany and fraud that hell ever contrived to ruin a nation.' Suffice it to add, that some of the 'directors' were expelled the house; others taken into custody; and the estates of several confiscated by act of parliament, after a certain allowance was deducted for each, according to their conduct and circumstances.

SOV'EREIGN (*souverain: Fr.*), a supreme ruler, or one who possesses the highest authority without control. A king or queen regnant.——An English gold coin, value twenty shillings; the standard weight of which is 5 dwt. 3·27 grs., or 123·374 troy grs. One twelfth of the sovereign consists of copper, which is added to give it hardness.

SOY, a dark-coloured sauce, prepared in China and Japan from the seeds of a sort of bean. It is eaten with fish, &c. A sauce of the same name is prepared in England.

SPA, a celebrated watering-place, about seven leagues from Aix-la-Chapelle. It has been long famous for its medicinal springs, which are mentioned by Pliny, and are six or seven in number. The term is now generally applied to all mineral springs.

SPACE (*spatium: Lat.*), in the abstract, mere extension.——*Space*, in Geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.——*Space*, in Mechanics, the line which a movable body, considered as a point, is conceived to describe by its motion.——*Space*, among Printers, a slip of wood or metal for making a space between words or lines.

SPADI'CEOUS, in Botany, an epithet for a kind of aggregate flower, having a receptacle common to many florets, within a spathe, as in palms, &c.

SPA'DIX (*Gr.*; from *spas*, I pluck off), in Botany, a receptacle bearing flowers surrounded by a sheathing bract or spade. Palms have a branching spadix, arums a simple one.

SPA'HI, or **SIPAHI** (a soldier: *Ind.*), one of the Turkish cavalry.

SPAN (*Sax.*), a measure taken from the space between the end of the thumb and the tip of the little finger, when extended. The span is estimated at three hands' breadths, or nine inches.——In seamen's language, a small line or cord, the middle of which is attached to a stay.

SPAN'DRIL, the space between the curve of an arch and the right lines inclosing it.

SPAN'IEL (*espagneul: Fr.*—from its supposed Spanish origin), the *Canis familiaris avicularius*, a name given to several varieties of dog, remarkable for sagacity and obedience; the largest and most beautiful of which is the Alpine or St. Bernard's breed; and the smallest the *Canis brevipitis*, usually called king Charles's breed, used as a lap-dog.

SPAR (*Spær: Sax.*), a mass of crystallized stone; any sort of earth which breaks easily into cubical or laminated fragments with polished surfaces.——A name given to the round pieces of timber used for the yards and topmasts of ships.

SPAR'ROW, the popular name of two British birds belonging to the genus *Pyrgita* or Passer, in the family of *Fringillidæ*: the *Passer montanus* or tree sparrow, and the *P. domesticus* or common house sparrow.

SPASM (*spasmos*; from *spao*, I draw: *Gr.*), in Medicine, an involuntary contraction of the muscular fibres, or that state of the contraction of muscles which is not spontaneously disposed to alternate with relaxation; it is generally accompanied by pain. When the contractions alternate with relaxation, they are called convulsions.

SPATHE (*Gr.*), in Botany, a sheathing bract surrounding floral organs usually splitting longitudinally, as in the arum.

SPATH'IC IRON (*spathē*, a broad blade of metal, &c.: *Gr.*), a mineral of a foliated structure, and a yellowish or brownish colour.

SPAT'ULA (the *dim.* of *spatha*, a blade: *Lat.*), an apothecary's instrument for spreading plasters, &c.

SPAT'ULATE (*last*), in Botany, an epithet for a leaf shaped like a spatula or a battledore, being roundish, with a long, narrow, linear base.

SPAV'IN (*espavent: Fr.*), in the Menage, a disease in horses, being a swelling or excrescence in the inside of a horse's hough, at first like gristle, but afterwards hard and bony.

SPEAK'ER, in the parliamentary sense, an officer who acts as chairman during a sitting.——*The Speaker of the House of Commons* is a member of the house, elected, at the commencement of a parliament, by a majority of votes to act as chairman or president, in putting questions, reading bills, keeping order, and carrying into execution the resolutions of the house. The Speaker is not to deliver his sentiments upon any question; but it is his duty to interrupt a member whose language is indecorous, or who wanders from the subject of debate; he may also stop a debate, to remind the house of any standing order, or established mode of proceeding, which he sees about to be violated. He, however, submits everything to the decision of the house. If the number of votes on the two sides of the question be equal, he may decide it by his own; but otherwise he cannot vote. When the house resolves itself into a committee, the chair is filled by a temporary chairman, and the Speaker is then capable of addressing the house on any subject, like a private member. He issues warrants to the Clerk of the Crown even during the recess, to make out new writs for the election of members when seats are vacant. He receives a salary of 6000*l.* a year, and he is supplied with a furnished residence. It is customary to make him a peer when he retires. In the House of Lords, the Lord Chancellor, keeper of the Great Seal, or other person holding the King's commission, is ex-officio Speaker; he can speak and vote on any question.

SPE'CIALTY (*specialitas*, peculiarity: *Lat.*), in Law, a term applied to a contract evidenced by an instrument under seal, thereby differing from what is called *simple contract*. Specialties are, after debts of record, entitled to priority in the distribution of assets, and are not presumed to be satisfied until after twenty years; while simple contracts are extinguished by the statute of limitations in six.

SPE'CIE, in Commerce, gold or silver coin, in distinction from paper money.

SPE'CIES (*Lat.*). In Natural History, such animals or vegetables as may be presumed to have descended from the same ancestors are said to belong to the same species. Such beings are liable to vary from the influence of circumstances. Whether the variation is indefinite or restricted within certain limits is a question upon which naturalists are divided, and the solution of which is attended with much difficulty. Different races from the same parents are called *varieties*. [See GENUS.] In Logic, a predicable, which is considered as expressing the whole essence of the individuals of which it is affirmed. This essence consists of two parts, the material part or *genus*, and the destructive part or *difference*: thus, a 'quadruped' has for 'genus' *animal*, and for 'difference' the having *four legs*. Species and genus are merely relative terms: thus, a horse belongs to the species quadruped, but a quadruped belongs to the species animal. A species, when predicated of individuals, stands in the same relation to them as the genus to the species. With regard to a lower species it is a genus, while with regard to a higher it is a species.

SPECIF'IC (*species*, a peculiar sort: *Lat.*), in Medicine, a remedy which either certainly cures some particular disease or is less fallible with regard to it than other remedies.

SPECIFICA'TION (*species*, a peculiar sort; and *facio*, I make: *Lat.*), the formal description of an invention for which letters patent have been obtained, required by the law to be filed in the patent office within six months of their date, otherwise they become void.——Also, amongst builders, the statement of the work required to be done, upon which the builder's contract is founded.

SPECIFIC GRAVITY. [See GRAVITY.]

SPE'CIMEN (*Lat.*), a sample or small portion of anything; intended to exhibit the kind and quality of the whole, or of something not exhibited.

SPEC'TACLES (*specto*, I look at: *Lat.*), an optical instrument for assisting the sight. With short-sighted persons, the crystalline humour, being too convex, brings the rays to a focus before they reach the retina; concave lenses remedy this, because they make the rays to enter the eye with more divergence, and therefore to be longer without coming to a focus. With elderly persons, the crystalline humour, being too flat, does not bring the rays to a focus as soon as they have reached the retina. Convex lenses remedy this, because they make the rays to enter the eye with less divergence, and therefore cause them to come sooner to a focus. Spectacles seem to have been first used about the latter end of the 13th century. [See OPTICS.]

SPEC'TRE (*spectrum*: *Lat.*), an appearance destitute of external reality affecting a person's organs of sight when the body is in an abnormal state.

SPEC'TROSCOPE (*spectrum*, *Lat*), *scopeo*, I examine: *Gr.*), an instrument employed for the examination of the spectra of the light from the sun, planets, and fixed stars, and for the measurement of the lines and bands of shade and colour, as to breadth, distance, and position. [See SPECTRUM, and SPECTRUM ANALYSIS.]

SPE'CTRUM. If a beam of sunlight is admitted into a dark room through a hole in a shutter, and allowed to fall upon a prism of glass, the emergent beam will be decomposed, and the solar or prismatic spectrum will be seen upon the wall or any white surface placed to receive it. At the bottom is red, and to this succeed orange, yellow, green, blue, indigo, and violet, each gradually changing into the next. This experiment proves that common light is not homogeneous, but compounded of rays of various colours, which become separated by reason of their different refrangibilities. The series of colours thus produced is called the solar spectrum. By means of a suitable contrivance, the coloured rays obtained from a sunbeam may be again collected into a beam of white light. If any of the colours of the spectrum be experimented on, it will be found that it cannot be decomposed; in other words, the original beam has been divided into homogeneous rays.

SPE'CTRUM ANAL'YSIS. It has long been known that the solar spectrum [see the last article] is marked by transverse *dark* lines, of which some hundreds have been counted. When the light of a flame is transmitted through a glass prism, the spectrum produced exhibits certain *bright* transverse lines whenever certain metallic substances are burnt in the flame. Experiment showed that the same substance always produced the same kind of line and in the same part of the spectrum. The presence of the lines in the spectrum might, therefore, be regarded as a proof of the presence of the respective metals. For example, if a small quantity of common salt (chloride of sodium) be burnt, a bright yellow line appears in the spectrum in a particular position. It has been ascertained that a quantity of sodium, less than the three millionth part of a milligramme, can be easily detected in this way, and thus this is infinitely the most delicate test that can be applied to the detection of sodium. Again, if a lithium compound be projected into the flame, two sharply-defined lines at once make their appearance, one being of a weak yellow, the other of a bright red. Thus a quantity of lithium, less than the millionth part of a milligramme, may be detected by the eye. Another curious result of this new method of analysis has been the detection of new elementary substances, the existence of which had not been previously imagined. It is by means of spectrum analysis that chemists have discovered the three metals, thallium, cæsium, and rubidium.

SPECULATION (*speculor*, I watch for: *Lat.*), in Commerce, the act or practice of buying articles of merchandize, or any purchaseable commodity whatever, in expectation of a rise of price and of selling the same at a considerable advance. In this it is distinguished from regular trade, in which the profit expected is the difference between the retail and wholesale prices; or the difference of price in the place where the goods are purchased, and the place to which they are to be carried for market. *Speculation* on a large scale, upon the principle of monopolising; or that kind of speculation which consists in the purchase and sale of shares in public companies, as well as 'dabbling' in the stocks , and a variety of other hazardous transactions which might be named; are different species of gambling, and are often no less ruinous.

SPEC'ULUM (*Lat.*), in Optics, any polished body employed for the purpose of reflecting light; but it is generally understood to mean a metallic surface, one of glass being termed a *mirror*.——SPECULUM METAL, or that of which the mirrors of reflecting telescopes are made, usually consists of two parts of copper and one of tin; and its whiteness is improved by a little arsenic. ——SPECULUM, in Surgery, an instrument for dilating and keeping open a wound, in order to examine it attentively.

SPEECH (*spæcan*, to speak: *Sax.*), the faculty of expressing thoughts by words or articulate sounds. [See LANGUAGE.]

SPELL (*spel*, a story or tale: *Ang. Sax.*), any form of words supposed to possess a magical virtue. Spells have been used in all ages; and were very common among the ancients.

SPELT (*speltre: Teut.*), a species of grain of the genus *Triticum;* called also German wheat.

SPEL'TER, the commercial name of zinc; about 67,000 tons of it are used per annum, throughout the world; of which 44,000 tons are rolled in sheets.

SPERM, or SPERMACE'TI, the unctuous matter contained in the head of the *Catodon macrocephalus*, the sperm whale or blunt-headed cacholot, which lives in the warmer seas and attains the length of eighty feet. Spermaceti oil is obtained from the blubber of this whale.

SPHA'CELUS (*sphakelos: Gr.*), in Medicine and Surgery, gangrene, or mortification of the flesh of a living animal. Also, *caries* or a decay of the bone. Hence, to *sphacelate*, to mortify; and *sphacelation*, the process of becoming gangrenous.

SPHENE, a mineral substance, found amorphous and in crystals. It is composed of nearly equal parts of oxide of titanium, silica, and lime. Its colours are various, inclining either to grey, yellow, brown, or different shades of green.

SPHERE (*sphaira: Gr*), in Geometry, a solid body, such as would be formed by the revolution of a circle about its diameter, as an axis Its surface is in every part equally distant from a point called its centre. Its area is equal to the perimeter of its great circle, multiplied by its diameter; and its solid contents are equal to its surface multiplied by one-third of its radius.——SPHERE, in Astronomy, the concave orb or expanse which invests our globe, and in which the heavenly bodies appear to be fixed, at an equal distance from the eye. The ancients called the orbits of the different planets, and the space occupied by the fixed stars, *spheres*; thus, the sphere of Jupiter, the sphere of the fixed stars, &c. In the Ptolemaic astronomy, the spheres were supposed to be solid, and transparent; to revolve about a common centre, independently of one another, each carrying its planet, &c. along with it.——SPHERE, in Geography, a representation of the earth on the surface of a globe; showing the position of the equator, ecliptic, meridian, &c. When the poles are in the horizon, the ancients called it a *right sphere*; when in the zenith, a *parallel sphere;* and when in any other position, an *oblique sphere.*

SPHER'ICAL, relating to the sphere. Thus *Spherical geometry*, that branch of geometry which treats of spherical magnitudes. ——*Spherical trigonometry*, that branch of trigonometry by which we compute the sides and angles of spherical triangles.——*Spherical triangle*, a triangle formed by the mutual intersection of three great circles of the sphere. *Spherical excess*, the sum by which any three angles of any triangle on the surface of a sphere or spheroid, exceeds two right angles.

SPHER'ICS, the doctrine of the sphere, particularly of the several circles described on its surface, with the method of projecting the same on a plane; the doctrine of its properties considered as a geometrical body.

SPHEROID' (*sphaira*, a sphere; and *eidos*, form: *Gr.*), a body or figure approaching to a sphere, but not perfectly spherical. A spheroid is either *oblate* or *prolate*. The earth is found to be an *oblate spheroid*, that is, flatted at the poles; whereas an opinion had been formed by some astronomers, that it was a prolate or oblong sphere.

SPHEROSIDE'RITE (*sphaira*, a sphere; and *sidēros*, iron: *Gr.*), in Mineralogy, a substance found in the basaltic compact lava of Steinheim. It is a granular variety of spathose carbonate of iron.

SPHER'ULE (*sphærula: Lat.*), a little globe or spherical body. Thus when mercury is poured upon a plane, it divides itself into a great number of minute *spherules*.

SPHER'ULITE (same *deriv.*), in Mineralogy, a variety of obsidian or pearl-stone, found in rounded grains.

SPHINC'TER (*sphinktor*; from *sphingo*, I bind: *Gr.*), in Anatomy, the name of several muscles, whose office is to shut or close the aperture round which they are placed.

SPHIN'GIDÆ, or **SPHINGI'NA**, in Entomology, a tribe of moths of which the genus *Sphinx* is the type. To this tribe belong the humming-bird hawk-moth (*Macroglossa stellatarum*), and the death's head moth (*Acherontia atropos*). They extract the honey of flowers by means of a long proboscis whilst hovering on the wing. The larva has 16 legs, as amongst the butterflies.

SPHINX (*Gr.*), in Antiquity, an emblematical figure, composed of the head of a man or woman, and the body of a lion, to which, when it was adopted by the Greeks, wings were added. There were also sphinxes with the heads of rams (*crio-sphinxes*) and hawks (*hieraco-sphinxes*). The most celebrated sphinx is the great one near the pyramids of Geezeh, which has forelegs 50 feet long.——According to the Grecian poets, a sphinx infested the city of Thebes; and devoured its inhabitants, until a riddle proposed by it was solved. This was done by Œdipus, who slew it, whereupon the Thebans in gratitude made him their king. This riddle was as follows: 'What creature is that which goes in the morning upon four; at noon, upon two; and in the evening, upon three legs?' Œdipus answered, 'It is man; who, in his infancy, crawls upon all four, walks afterwards on two, till old age brings him to his staff, which constitutes three legs.'

SPI'CA, a star of the first magnitude in the Virgin; the α *Virginis* of astronomers.

SPI'CULA (the plural of *spiculum*, a javelin: *Lat.*), accretions of silicious or calcareous particles embedded in and supporting the soft fleshy portions of many animals of low organization. The mantles or outer coats of several shell-less molluscs contain calcareous spicula, and the bark of many flexible corals (*Gorgoniadæ*), and some stony corals (the true coral, for example) are composed entirely of these bodies. The skin of some echinoderms, especially the worm-like genera, is strengthened by calcareous spicula. The skeletons of a great number of sponges are composed of these bodies, which in one division are silicious, in another calcareous. Strictly speaking the term should be applied to the needle and pin-shaped forms, but it has been extended to every form of these bodies, hooked tri radiate, stellate, egg-shaped, wheel-shaped, &c. They are frequently very minute, and their regular forms are then pretty objects for the microscope.

SPIDERS form the order *Araneidea* in the class *arachnida*. They are distinguished from other articulata by the head being continuous with the chest and forming a part called cephalo-thorax, by the possession of falces, organs on the head which take the place of antennæ, and armed with claws perforated with a poison duct, and by the possession of four pairs of legs. The abdomen consists of one piece, and at the posterior end are situate the perforated prominences called spinnerets, through which the lines issue that form the web At the anterior end of the underside of the abdomen are placed the respiratory apertures. The eyes are simple, not compound, and are two, six, or eight in number. The sexes are distinct, the females being usually larger. Their eggs are laid in clusters, and are usually protected by some sort of nest or cocoon made of web. The young do not undergo any proper metamorphoses, but they change their integument several times before they arrive at maturity. Spiders are found in all parts of the world, the number of species being great. Some of them possess the poisonous matter in such quantity that their attack is dreaded by man.

SPIDER MONKIES are so called on account of the slenderness of their bodies and limbs. They live in trees in South America. The tail is a prehensile organ of wonderful flexibility, which is always in motion coiling and uncoiling. By this they hang from a branch, or swing themselves from tree to tree. The absence of a thumb from the hands is another remarkable part of their structure. They are mild in disposition and easily tamed. They form the genus *Ateles* of zoologists.

SPI'DERWORT, a name given to herbaceous plants of the genus *Tradescantia*, on account of the glutinous nature of their juice, which may be drawn out in long threads.

SPIKE (*spica: Lat.*), in Botany, a species of inflorescence, in which sessile flowers are placed on a simple peduncle, as in wheat, lavender, &c.——In Gunnery, *to spike a gun*, is to fill up the touchhole of a piece of ordnance, by driving a nail forcibly into it, to render it unserviceable.

SPI'KENARD (*spica nardi*, a spike of nard: *Lat.*), a plant brought from the East Indies, and therefore sometimes called *nardus Indica*. The spikenard of the ancients is supposed to have been the *Nardostachys Jatamansi*, nat. ord. *Valerianaceæ*, the root of which is, at present, much esteemed in the East as a perfume.

SPI'NAL CORD, sometimes called Spinal Marrow, in Anatomy, is that part of the nervous system which is inclosed in the spinal column of vertebrate animals. At its upper end it is in connection with that part of the human brain called the *medulla oblongata*, and is continued to the first or second lumbar vertebra, giving off in its course thirty-one pairs of nerves, each having two roots. It has been proved that sensation depends upon the posterior root, and the power of voluntary motion upon the anterior root. The spinal cord is composed of white and gray nervous matter, the white being on the outside.

SPINE (*spina*, the back bone: *Lat.*), the column of bones in the back of the vertebrate animals. [See VERTEBRÆ.]——*Spine*, in Botany, a thorn, or sharp process from the woody part of a plant. It differs from a *prickle*, which proceeds from the bark. A *spine* sometimes terminates a branch or leaf; and sometimes is axillary, growing at the angle formed by the branch or leaf with the stem. The wild apple, the sloe, &c., are armed with *spines* or *thorns*; the gooseberry-bush, the bramble, and the rose have *prickles*. Spines are branches the development of which has been arrested. Aculei or prickles are a kind of hardened hair.

SPINE'L (*spinelle: Fr.*), a subspecies of *ruby*, of different colours, red, brown, yellow, and sometimes blue; it consists chiefly of alumina and magnesia, with a colouring matter consisting sometimes of oxide of chromium, but generally of oxide of iron.

SPINELLA'NE, a dodecaëdral variety of *Zeolite*, of a blueish or brownish colour; and consisting of silica, alumina, and soda.

SPINE'T (*espinette: Fr.*), a musical stringed instrument, now no longer in use. It differed from the harpsichord in little else than size. Like that instrument, it was somewhat in the form of a harp, and was, indeed, called a *couched harp*.

SPIN'NING, in Manufactures, the act or art of uniting fibres of silk, flax, hemp, wool, hair, or other materials, into thread. It is either performed on the wheel with a distaff and spindle; or by machinery. Among the Greeks and Romans spinning was the chief employment of the women; the rites of marriage directed their attention to it; and the distaff and fleece were not only the emblems, but the objects of the most important domestic duties of a wife.

SPIN'NING JENNY, a machine invented by Hargreaves, in 1767, which enabled one person to spin from 80 to 120 threads as easily as a single thread previously. It was adapted for spinning only the softer descriptions of yarn, which were used in *weft*; being incapable of giving the firmness and hardness required in that which was used as *warp*; and it was soon superseded by the *spinning frame* of Arkwright, which could spin any number of threads, of any degree of hardness and fineness, and required only to be fed with cotton, and to have the threads joined when broken.

SPI'NOZISM, the doctrines or principles of Spinoza, a Jew of Amsterdam, born in 1634. He attempted to deduce from a few axioms, that 'there can be no substance but God; whatever is, is in God; and nothing can be conceived without God.'

SPIN'STER, in Law, the common title by which an unmarried woman without rank or distinction is designated. Curiously enough we find on the tombs of *married* women amongst the ancient Romans, the epithet 'lanifica,' spinster. King Alfred in his will called the women of his family 'the spindle side'; and Egbert, when he entailed his estates on his male descendants to the exclusion of the females, said: 'to the spear side, and not to the spindle side.'

SPI'RACLES (*spiraculum*, from *spiro*, I breathe: *Lat.*), in Entomology, the pores by which air enters the tracheæ of insects.

SPI'RAL (*speira*, anything wound round another: *Gr.*), in Geometry, a curve which winds round a centre, and in its progress continually increases its distance from that centre. The fusee or spring of a watch give a good idea of this curve. There are various kinds of spirals, which have received their names from their inventors or their properties; thus the *Spiral of Archimedes*, the *hyperbolic spiral*, &c. [See HELIX.]

SPIRE, in Architecture, a steeple that continually diminishes as it ascends, whether conically or pyramidally. The highest spire in England is that of Salisbury, 404 feet above the level of the ground, or 64 feet higher than the cross of St Paul's, and double the height of the Monument, near London bridge.——The term *spire* was used by the ancients for the base of a column, and sometimes for the astragal or torus.

SPIR'IT (*spiritus: Lat.*), in Metaphysics, an incorporeal being or intelligence.

SPIR'ITS, any inflammable liquor obtained by distillation; as brandy, rum, &c. Ordinary spirits contain from 50 to 52 per cent. of alcohol; spirits of wine, from 62 to 67 per cent.; rectified spirits, from 82 to 85 per cent. What is called *proof spirit* contains 49¼ per cent. by weight of real alcohol, and has a specific gravity at 60° Fahr. of 0·9198. When spirit is said to be any number over proof, the expression means that 100 gallons of it would take that number of gallons of water to reduce it to proof strength; thus 100 gals. of spirit 10 over proof, would require 10 gals. of water to reduce it to proof; the result of the mixture being 110 gals. at proof. [See ALCOHOL.]

SPIRITUAL COURT, one held by a Bishop or other ecclesiastic, or their representative.

SPIRIT LEVEL. [See LEVEL.]

SPIR'ITUALISM (*spiritus*, a spirit: *Lat.*), as distinguished from *Materialism*, that system which supposes everything real, to be spirit: what is called the external world being a succession of notions impressed on the mind by the Deity—which was the opinion of Berkeley; or a mere educt of the mind—which was that of Fichte.

SPLANCHNOL'OGY (*splanchnon*, the internal parts of the body; and *logos*, a discourse: *Gr.*), in Medical science, a treatise or description of the viscera; also the doctrine of diseases of the internal parts of the body.

SPLEEN (*splēn: Gr.*), in Anatomy, a soft, spongy substance, situated on the left side, between the eleventh and twelfth false ribs, and covered with a firm membrane, arising from the peritoneum. It is of an oval form, about one-fifth smaller than the liver: hollow towards the stomach, and convex towards the diaphragm and ribs; it is, however, not unfrequently irregular, and has many fissures. The use of the spleen has been much controverted; but the most probable opinion seems to be, that it serves to render more fluid the blood, out of which the bile is to be afterwards secreted; and that by this means obstructions, which must otherwise be frequent, are prevented, and the secretion of the bile promoted. In figurative language we use the word spleen for ill-humour; as, to vent one's *spleen*.

SPLENI'TIS (*Gr.;* from *splēn*, the spleen), in Medicine, inflammation of the spleen.

SPLENT (*splint*, a splinter: *Dan.*), in the Veterinary art, a callous substance or insensible swelling on the shank-bone of a horse.

SPLICE, a term in common use with seamen, &c., signifying to separate the strands of the two ends of a rope, and unite them by a particular manner of interweaving them; or to unite the end of a rope to any part of another by a like interweaving of the strands

SPLINT (*splint*, a splinter: *Dan*), in Surgery, a piece of wood or paste-board shaped so as conveniently to support a broken or debilitated limb.

SPLINTERY, in Mineralogy, that fracture of minerals which is almost even, but exhibits small splinters or scales thicker at one end than the other, and adhering by their thicker end to the broken surface.

SPOD'UMENE (*spodos*, wood ashes: *Gr*), a mineral occurring in laminated masses easily divisible into prisms with rhomboidal bases; the lateral faces shining and pearly, the cross fracture uneven and splintery. Before the blowpipe it exfoliates into little scales of an ash colour, whence its name. It consists of silica, alumina, and lithia. It is called also *triphane*.

SPON'DEE (*spondeios*, from *spondē*, a libation—at which slow, solemn melodies, chiefly in this measure, were used: *Gr.*), in the Latin and Greek prosody, a poetic foot of two long syllables.——*Spondaic Verse*, an hexameter line in which the two last feet are spondees, instead of being a dactyl and a spondee.

SPONGES, aquatic animals of such low organization that their vegetable nature has been frequently asserted. They may be roughly described as a mass of uniform animal matter (sarcode) without any visible organs, disposed upon and around a skeleton or frame-work which may be calcareous, silicious or horny and elastic, the last being the condition of the skeleton in the sponges which we employ for domestic purposes. In the great majority of the calcareous and silicious sponges the skeleton is composed of 'spicula,' that is, detached pieces shaped like needles, pins, crosses, stars, anchors, hooks, and many other forms. These are pretty objects for the microscopic observer. The external forms of sponges are very varied, cup-shaped, finger-shaped, bread-like, encrusting, &c.; and the size varies from a minute speck to the dimensions of three or four feet. Only one genus (*Spongilla*) has been found in fresh water; the rest are marine, and invariably attached to rocks, stones, or plants. They derive sustenance from the medium in which they live, which conveys their food (perhaps both minute animal and vegetable particles) into and along the canals by which they are permeated. Ciliary action has been detected in some of them, and perhaps it exists in all the species. They are propagated by ova, by gemmation, and by spontaneous division. Sponges are found fossil in the chalk, and are frequently embedded in the flints of that formation. The sponges of commerce are chiefly procured from the Mediterranean and the American coast, being brought up by divers from considerable depths. When the gelatinous matter has been removed from the fibrous skeleton it is washed and dried. The coarse kind comes from the Bahamas and Florida; the finer kinds, known as Turkey sponge, from the Mediterranean, the best being procured at the Cyclades. The divers will sometimes descend to the depth of 30 fathoms for them. About 500,000lbs. of sponge are annually imported into England.

SPON'GIOLE (*spongiolus*, literally, a little sponge: *Lat.*), in Vegetable Physiology, organs which derive their name from being composed of cellular spongy tissue. They are situated at the end of the root, and by imbibing the fluids which are in contact with them, enable plants to absorb the nourishment and moisture necessary to their growth.

SPON'SOR (a surety; from *spondeo*, I pledge myself: *Lat.*), one who binds himself to answer for another, and is responsible for his default. Hence, *sponsor*, in baptism, is a surety for the moral education of the child baptised

SPONTA'NEOUS (*spontaneus*; from *sponte*, of one's own accord: *Lat.*), an epithet for things that act by their own impulse, or without any apparent external agency; as, the spontaneous ignition of certain substances which, of themselves, will burst into a flame.

SPOON'BILL, a name given to some grallatorial birds belonging to the genus *Platalea*, of which the white species is very common in the old continent, and the roseate in the new. It is named from the shape of its bill, which is somewhat like a spoon or spatula.

SPOON'-DRIFT, a sea term for a showery sprinkling of salt water, swept from the surface in a tempest.

SPORAD'IC (*sporadikos*, scattered: *Gr.*), in Medicine, an epithet for such diseases as attack but few persons at a time; in contradistinction to *epidemic*.

SPORANGIUM (*spora*, seed; and *angeion*, a vessel: *Gr.*), the case in which the spores or ovules of the ferns, mosses, and many other cryptogamic plants is contained.

SPORES, or SPORULES (*spora*, a seed: *Gr.*), cellular bodies in the cryptogamic plants from which new plants are produced. They are equivalent to the ovules of the higher orders of plants. They have no definite points of growth, but send forth young plants from any part of their surface

SPORI'DIA (*spora*, seed: *Gr.*), spores united in definite numbers.

SPOTS, in Astronomy, dark places observed on the sun, moon, and planets. The spots on the sun vary; whilst those on the moon and planets remain the same, and by their motion make the rotation of those bodies manifest. [See SUN.]

SPOUT'ING FLUIDS. If an aperture is made in the upper surface of any pipe, and communicating with a reservoir of fluid, the latter, but for the resistance of the air, and the friction at the aperture, would spout to a height equal to that of the highest particle of fluid in the reservoir. If there is an aperture in the side of a vessel, which is full of water, the latter will spout to the greatest distance when the aperture is in the middle, and, to the same distance, from apertures which are equidistant from the middle. If there is a short pipe in the aperture, the fluid will spout from it to the greatest distance, when it is inclined to the horizon at an angle of 45°, and to the same distance, with inclinations equidistant, from 45°, for example, from inclinations of 40° and 50°.

SPRING, the season of the year when increasing solar heat restores the energy of vegetation. In the northern hemisphere, it begins when the sun enters Aries, that is, about the 21st of March; and ends at the summer solstice.——*Spring*, in Mechanics, denotes a thin piece of tempered steel, or other elastic substance; which, being wound up, serves to put several machines in motion by its elasticity: such is the spring of a clock, watch, &c.—*Spring*, in Physical Geography, a fountain of water, or issue of water from the earth, or the basin of water at the place of its issue. From *springs* proceed rivulets, and rivulets united form rivers. Rain penetrates the ground, and oozes into and through certain strata, but, being obstructed by other strata, it forms cavities and subterraneous reservoirs at various depths, many of which, when full, force their way out of the ground, and constitute springs. That reservoirs of water exist beneath the surface of the earth is manifest from what is observed in sinking Artesian wells, which see.

SPRIT'-SAIL, in Vessels, a sail attached to a yard which hangs under the bowsprit. A small boom or pole which crosses the sail of a boat diagonally, from the mast to the upper sternmost corner, is termed a *sprit*.

SPRUCE FIRS, coniferous trees belonging to the genus *Abies*. They are distinguished from pines by the cones being pendent, the carpels not being thickened at the tip, and the solitary leaves more or less two ranked. The Norway spruce (*A. excelsa*) is a lofty and valuable timber tree. The black and white spruce (*A. nigra* and *A. alba*) are Canadian trees. From the young twigs of the former spruce beer is made. The red spruce (*A. rubra*) is a native of Nova Scotia; the Hemlock spruce (*A. canadensis*) of North America.

SPRUCE-BEER, a liquor prepared by fermenting a mixture consisting of water, molasses, bruised pimento and ginger, and essence of spruce; the last being prepared by boiling the young shoots of the *Abies nigra*, and concentrating the decoction by evaporation.

SPUNK, or **TOUCHWOOD**, a name given to some fungi belonging to the genus *Polyporus*, especially *P. fomentarius*, soaked in a solution of nitre; it is used for kindling matches and tobacco, under the name of *Amadou* or *German tinder*.

SPURGE (*épurge: Fr.*; from *purgo*, I purge: *Lat.*), a name given to plants belonging to the genus *Euphorbia*.——*Spurge-laurel*, the *Daphne laureola*, a shrub.——*Spurge-olive*, the mezereon, a shrub of the genus *Daphne*.

SQUAD'RON (*escadron: Fr.*), in Military affairs, a body of cavalry usually from 100 to 200.——*Squadron of ships*, a division of a fleet, employed on a particular expedition, and commanded by a vice or rear-admiral, or a commodore.

SQUA'LUS (*Lat.*), in Ichthyology, a genus of sharks. [See SHARK.]

SQUARE, in Geometry, a quadrilateral figure, whose angles are right angles, and sides equal: that is, making its angles right angles. Also the area formed by means of a given lineal measure: as a square foot, a square yard, &c.——*Square*, in Arithmetic, the product of any number multiplied by itself. ——Among Mechanics, an instrument for squaring their work.——In Military affairs, a body of soldiers formed into a square.——*Square-root*, in Arithmetic, a number which, multiplied in itself, produces the square number: thus, 2 is the square-root of 4.——*Square-rigged*, is said of a vessel when her principal sails are extended by yards suspended by the middle, and not by stays, gaffs, booms, and lateen yards. Thus a ship and brig are square-rigged vessels.——*Square-sail*, a sail extended to a yard suspended by the middle.

SQUAR'ROUS (*squarrosus*, rough: *Lat.*), in Botany, a term applied to parts of plants which are covered with processes that spread at right angles. *A squarrous calyx* consists of scales very widely divaricating.

SQUILL (*squilla*; from *skilla: Gr.*), the name of plants belonging to the genus *Scilla*, nat. ord. Liliaceæ. From the bulbous root of some of the species a medicinal preparation is made. In large doses, squill is a purgative and emetic; in smaller, a powerful expectorant; and in combination with other remedies, a diuretic.

SQUIR'REL, the name given to small rodent mammals of the genus *Sciurus*, characterized by their lower incisors being very compressed, and the tail being long and bushy. The species are found in many parts of the world, inhabiting woods and feeding on nuts and fruits. The British species (*S. vulgaris*) lays up a store of nuts for winter, in hollow trees or in the earth. It displays great agility in leaping from branch to branch.

STA'BAT MA'TER, the commencing words of a Latin hymn, of the Roman Catholic Church, which has been repeatedly set to music by the great masters.

STACCA'TO (separated: *Ital.*), in Music, a term indicating that the notes to which it is affixed are to be detached, in a marked way, from each other. It is nearly the same as *Spiccato.*

STAC'TE (*staktē;* from *stazo,* I fall in drops: *Gr.*), a fatty, resinous, and very odoriferous kind of gum, of the nature of liquid myrrh. It is very valuable when pure; but it is supposed that we have none but what is adulterated, and that what is so called is liquid storax.

STA'DIUM (*stadion,* literally that which stands fast; a standard: *Gr.*), in Antiquity, an open oblong area, for gymnastic exercises. Vitruvius describes it as a space 125 geometrical paces long, terminated at the two extremes with two posts, called by the Romans *carcer* and *meta.* Around the *stadium* was raised a mound of earth, where the spectators were placed to see the feats of the athletæ. There were also other *stadia* covered over with colonnades and porticos, serving for the same exercises in bad weather. —— *Stadium,* an ancient Grecian measure, the extent of which is not certainly known; and which, probably, was different in different places. Eratosthenes calculated the length of a meridian to be 250,000 stadia; which, if his measurement was correct, would make a stadium to be the tenth of an English mile. Possedonius calculated the length of the meridian to be 240,000 stadia; which would give 9½ stadia to the mile.

STADT'HOLDER (*stadhouder,* city holder: *Dut.*), the title formerly given to the commander-in-chief of the forces belonging to the Republic of the United Netherlands. William IV., Prince of Orange, was constituted the first general hereditary stadtholder, in 1747; the office ceased at the French conquest; and in 1814 the head of the House of Orange was elevated to the *regal* dignity, which has been retained by his successors.

STAFF, in Military affairs, an establishment of officers in various departments, attached to the commander of an army. The staff is the medium of communication between the commander-in-chief and every department of an army.——An ensign of authority; a badge of office; as, a constable's *staff.*

STAG, the male of the deer kind.

STAG BEETLE, a common beetle in the south of England, so called from the large snagged and forked mandibles somewhat resembling the antlers of a stag. The male is sometimes nearly three inches long, and of a brownish black colour. It is the *Lacunus cervus* of entomologists.

STAGE (*stage,* a floor: *Fr.;* from *statio,* a station: *Lat.*), in the Drama, the place of action and representation; included between the pit and the scenes; and answering to the *proscenium,* or *pulpitum* of the ancients. The word *stage* also often implies the whole dramatic art in composition and performance.

STA'GYRITE, an appellation given to Aristotle from Stagira, a town in Macedonia, the place of his birth.

STALAC'TITES (*stalaktos,* dropping: *Gr.*), elongated concretions of carbonate of lime, hanging from the *roofs* of caves. It is formed by the percolation of water holding bicarbonate of lime in solution. The carbonate is left in the solid form, when the second atom of carbonic acid and the water evaporate.

STALACTIT'IC, in the form of stalactites, or pendent substances like icicles.

STALAG'MITE (*stalagmos,* a dropping: *Gr.*), concretions produced on the *floors* of caves, in the same way, and from the same cause, as *stalactites* [which see]. Sometimes the stalactites and stalagmites unite and form pillars.

STALK'ING, a term used in sporting, and applied to a kind of screen, and sometimes to a horse, to hide the sportsman while he gets within shot. Hence the word *stalking-horse* is used for a pretence.

STALL, the seat of a dignified clergyman, in a cathedral.——Also, an open shop in a market or fair.——*Stallage,* the right of erecting stalls in fairs; or rent paid for them. When they are fixed in the ground the money paid is called *pickage.*

STA'MEN (*Lat.*), in Botany, one of the bodies in a flower which secrete pollen, the fructifying principle. Whatever their number, for they vary considerably in this respect, the stamens form a whorl between the petals and the pistil. Each consists of the *filament* and the *anther,* the latter containing the fine dust called *pollen:* the filament or stalk is sometimes absent.

STAM'INIFEROUS, in Botany, an epithet for those flowers which have stamens, and usually applied to those in which the pistils are wanting.

STAMP, a mark set upon things chargeable with duty to government, as evidence that the duty is paid; as, the stamp on a newspaper, the stamp on a bond or indenture, &c.——Any instrument for making impressions on other bodies.

STAN'DARD, that which is established as a rule or model, by the authority of respectable opinions, or by general consent. Thus, Addison's writings furnish a good *standard* of pure, chaste, and elegant English composition.——In Botany, the upper petal or banner of a papilionaceous corolla.——In Commerce, the original weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try weights used by particular persons in traffic. The standard of gold coin is 22 parts of fine gold and 2 of alloy, in the pound troy. The standard of silver is 11 oz. 2 dwts. of pure silver and 18 dwts. of alloy of copper. Whether gold or silver be above or below the standard is found by assaying, and the hydrostatical balance. The standard of measure, made by Bird in 1760, to which great authority was attached, was destroyed by the fire which consumed the two Houses of Parliament, in 1834.——STANDARD, in Military affairs, a flag or banner borne as a signal for the forming of troops into a body. ——In Ship-building, an inverted knee placed upon the deck instead of beneath it, with its vertical branch turned upward from that which lies horizontally.——STANDARDS, in Horticulture, a term used to distinguish such fruit-trees as are not trained against walls or grow in espaliers

STAN'NARIES (*stagnum*, tin: *Lat.*), the mines and works from which tin is dug and purified. Those of this country are found chiefly in Devonshire and Cornwall. ——The Court of Stannaries is a court of record of limited jurisdiction for the administration of justice amongst the tin miners of Devon and Cornwall. It is of great antiquity, and has been regulated by several acts of Parliament. The court is held at Truro, and the presiding judge is termed the Vice Warden. From his decision there is an appeal to the Lord Warden, assisted by two or more assessors, members of the judicial committee of the Privy Council, or judges of the Court of Chancery, or Courts of Common Law at Westminster.

STAN'ZA (a station: *Ital.*), in Poetry, a number of lines or verses connected with each other; being a portion of a poem containing every variation of measure in that poem. Stanzas are said to have been first used in Italian poetry.

STA'PLE (*stapel: Belg.*), a settled mart or emporium for the sale of certain articles. The king's staple, as it was called, was formerly established in certain ports of towns in England, and certain goods could not be exported, without being first brought to these places to be rated and charged with the duty imposed upon them. The principal commodities on which customs were levied were wool, skins, and leather, which being called '*staple* commodities,' the term in time was applied to the principal commodities produced by a country either for exportation or home consumption.——The word *staple* is also used to signify the thread or pile of wool, cotton, or flax; as, cotton is of a short, long, or fine *staple*.

STAR'-APPLE, a globular or olive-shaped fleshy fruit, inclosing a stone of the same shape. It is produced by a tree of the genus *Chrysophyllum*, nat. ord. *Sapotaceæ*; and is grown in the warm climates of America. It is eaten by way of dessert.

STAR'BOARD, the right hand of a ship or boat, when looking towards the head or stem; *port* being employed for the opposite side.

STAR'-CHAMBER, formerly a court of criminal jurisdiction at Westminster, so called from its roof being ornamented with gilt stars. This court took upon itself to decide upon those cases of offence with regard to which the law was silent. It passed judgment without the intervention of a jury; and differed from all other judiciary courts in this, that the latter were governed only by the common law, or immemorial custom, and acts of parliament; whereas it often admitted for law the proclamations of the king in council. This court was abolished by stat. 16 Chas. I.

STAR'-FISHES, a section of Echinodermata, one of the classes of radiate animals. They abound on all coasts, and the majority may be at once recognised by their five arms or angles, diverging from a common centre. Sir Thomas Browne long ago noticed how 'Nature among sea-stars chiefly delighteth in five points.' They may be divided into three tribes.—1. *Crinoidea*, to which the fossil Encrinites, and the living PENTACRINUS and COMATULÆ belong. 2. The *Ophiuridea*, and 3. the *Asteridea*. The animals included in these two tribes have a leathery, flexible integument, with or without calcareous plates, and a mouth which is placed at the middle of the underside. To the Ophiuridea belong those species with a discoidal body and five long arms, into which the visceral cavity does not enter; the sand-stars and brittle-stars of our coasts are examples. The Asteridea include the species with pentagonal or polygonal bodies, having the angles more or less extended in the shape of arms, which contain prolongations of the stomach; the cross fishes of our shores afford examples. The animals of both these tribes effect locomotion by means of cirri or threadlike suckers, with which the arms are furnished, and by which they pull themselves slowly along.

STARS. The members of our solar system have been treated of under the head PLANETS, and under the name of each; in the present article the fixed stars, those external to our system, will be considered. The division of the stars into constellations is only to be considered as a means of more readily referring to the more remarkable objects. This is effected by adding to the name of the constellation a letter from the Greek alphabet, as *Alpha Lyræ*, *Beta Orionis*, the name of the constellation being usually in Latin. The easiest method of acquiring a knowledge of them is to use a celestial globe, which can be compared with the heavens at the different seasons of the year. [See CONSTELLATIONS.] The stars have been usually classed according to their apparent lustre or magnitude. No more than six, or, under particularly favourable circumstances seven, magnitudes can be seen with the naked eye; but with the aid of the telescope much smaller stars can be perceived. There are about 20 stars of the first magnitude, 70 of the second, 220 of the third, 500 of the fourth, 690 of the fifth, and 1500 of the sixth. Whatever the apparent magnitudes of the stars may be, it is only by the intensity of their light, and not by any measurable diameter, that they are distinguished from one another. The higher the power of the telescope the more do they contract into minute shining points. Sir John Herschel has proposed a new method of expressing the magnitudes of the stars; namely, by determining photometrically the comparative intensities of their light. When this was done it was found that among stars of the first magnitude, some emitted only one-eighth of the light of others. It is a matter of importance to ascertain the intensity of the light of each considerable star, on account of the changes which the light of some of them undergoes. The seven stars of the Great Bear, for example, are continually changing their brightness, and they take it in turn to be one brighter than the others. Again, some stars vary periodically in light and lustre; *Algol* [which see] is one of these stars. A star in the centre of a nebula in Argus (η *Argi*) was of the fourth magnitude in 1677, but in 1844 it had become nearly as bright as Sirius. It is now gradually losing its brilliancy. It is also on record that several stars have suddenly appeared and afterwards vanished from the heavens. As to the distribution of the stars in space, it may be remarked that those of the three or four first classes seem to be pretty uniformly scattered over the heavenly vault; but looking at all magnitudes visible to the naked eye, they increase rapidly as we approach the milky way. From various observations that have been made, it seems probable that the solar system is placed near the centre of a comparatively shallow layer of stars, and that we look in the direction of its top and bottom when we cast our eyes on the heaven on each side of the Milky Way, and in the direction of its sides or edges when we look upon that luminous band. [See GALAXY.] The total number of stars must be considered infinite. Sir W Herschel counted 238,000 stars in the field of his 20 feet reflector in 41 minutes of time, and it is probable that the more powerful telescopes constructed since his day render 100 millions visible. In many clusters whose area does not exceed the tenth part of that covered by the moon, from ten to twenty thousand stars have been counted With regard to the distance of the stars, the only mode by which the interval which separates them from us can be calculated is by ascertaining their parallax [see PARALLAX], for which the best instruments and the most careful observations are needed The largest amount of parallax yet discovered is that of α *Centauri*, but this does not amount to one second; that of *Sirius*, which emits four times the light of α *Centauri*, is less than the sixth of a second; whilst that of *Capella* is only about the 22nd of a second. It must be concluded that the stars are suns shining by their own light, for since they are destitute of measurable discs, the light they emit cannot be reflected. Assuming the parallax of Sirius to have been correctly ascertained, it has been calculated that his intrinsic splendour is more than 224 times that of our sun. It was long believed that the appearance of double stars, and even of three or more, which seem to form systems, was due to their being situated in the same line of view; and in some instances, this may be the case. But it is now ascertained beyond a doubt that there exist sidereal systems, composed of two, three, four, and even five stars, revolving round each other, or round a common centre. In addition to such motions it has been discovered that some stars have a proper motion, that is, they are carried bodily away from their places along unknown paths. This motion is small, but it has been distinctly made out. Thus 61 *Cygni* has moved 4m. 23s. during the last 50 years [See GALAXY, NEBULÆ, MAGELLANIC CLOUDS.]

STAR′ STONE, a rare variety of *sapphire*, which, when cut and viewed in a direction perpendicular to the axis, reflects light in the form of a star.

STAR′-WORT, a plant of the genus *Aster*. The *yellow star-wort* is of the genus *Inula*.

STARCH (*stärke: Ger.*), one of the most common vegetable principles; but, in Commerce, the name is restricted to that obtained from wheat. In manufacturing wheaten starch the grain is ground, and the meal is diffused through water, where it undergoes a slight fermentation and acquires a peculiar sour smell: the gluten and albumen partially separate in the form of a viscid scum, and the starch which subsides as a fine white powder is washed, allowed to settle, drained, cut into squares, and dried Starch may be obtained from potatoes, by rasping them, carefully diffusing through water, agitating and decanting, allowing the starch to settle, washing, draining, and drying. The blueness of commercial starch arises from the addition of a little *smalt* Starch forms a gelatinous compound with water heated to 175°, and the solution, though greatly diluted, is rendered blue by iodine, which is the test of starch.——*Arrow root* is the starch of the *Maranta arundinacea*; *sago*, that of the *Sagus fariniferus*, an East Indian palmtree and other trees; *tapioca* and *cassava*, that of the *Jatropha manihot*. The different varieties of starch appear, under the microscope, as rounded or oval grains, which consist of little sacs containing the starchy matter. They exhibit a beautiful play of colours in the polariscope. Cold water has no effect upon these sacs, but hot water swells them and causes them to burst, whereupon they are converted into a gelatinous mass In the process of germination and by means of chemical agents, starch may be changed into *dextrine*, a gum-like body; and also into a species of sugar.

STAT′ICS (*statikos*, belonging to a state of rest; from *istēmi*, I stand: *Gr.*), the doctrine of the *Equilibrium of forces*, that branch of Physics which treats of bodies *at rest*. Dynamics treats of bodies *in motion*. *Equilibrium* may be produced in three ways. 1. By two equal and opposite momenta [see MOMENTUM], as with the lever. 2. By *composition of forces* [which see], as when a body is acted on by any number of forces, represented in quantity and direction by *all* the sides of any rectilineal figure taken in succession. 3. By the principle of *virtual velocities* [which see]; that is, when the forces which act on a body are in the inverse ratio of the respective spaces which the points at which they act would describe, were the equilibrium from any cause slightly disturbed.

STA′TIONARY (*stationarius*, pertaining to a fixed station: *Lat.*), in Astronomy, an epithet applied to the appearance of a planet, when it seems to remain on the same point of the zodiac for several days. As the earth, from whence we behold the motions of the planets, is out of the centres of their orbits, the planets appear to proceed irregularly; being sometimes seen to go forwards, that is, from west to east; and sometimes backwards, or from east to west, which is called their *retrograde* motion. Now between these two states there must be an intermediate one, in which the planet neither appears to go backwards nor forwards, but to stand still. [See PLANET.]

STATIONARY ENGINE. A fixed steam engine such as is used on a railway, for drawing a train up an inclined plane, by means of a rope. The word is used in opposition to *Locomotive*.

STATIS'TICS (*status*, condition: *Lat.*), a science which exhibits the conditions of a country, with regard to its extent, population, industry, wealth, and power. It includes the natural and acquired capabilities of productions; the quantity and value of the various articles of utility and convenience which it possesses, and annually produces; the number and classes of its inhabitants, with their respective incomes; with the institutions for the government, improvement, defence, and maintenance of the population. It has much in common with *geography* and *politics*, and includes what is termed political arithmetic. The accounts and details given, to be of any value, must be accurately drawn up; and the circumstances to which they are due must be clearly explained. In a work on statistics ought to be included the condition of the poor; the state of schools and other public institutions of utility; with every other subject, the knowledge of which may be useful in ascertaining the moral condition and political strength of a country, its commerce, arts, &c.

STA'TUS QUO (the state in which: *Lat.*), that condition between two or more belligerents, who have entered into a treaty by which they are restored to the same state as before the war, with regard to their territories, fortresses, &c.

STA'TUTES (*statut: Fr.:* from *statuo*, I decide: *Lat.*), acts of parliament made by the three estates of the realm, and which are either public or private. *Statutes* are distinguished from *Common law*. The latter owes the obligation it imposes to the principles of justice, to long use, and the consent of a nation. The former owe their binding force to a positive command or declaration of the supreme power. The courts of Westminster must take cognizance of the public statutes without their being specially pleaded, but not so of private statutes.

STAU'ROLITE (*stauros*, a cross; and *lithos*, a stone: *Gr.*), in Mineralogy, the *cross* stone or *Harmotome*. It is a silicate of baryta and alumina, with traces of lime and potash; and consists of small quadrangular prisms, crossing each other.

STAU'ROTIDE (*stauros*, a cross; and *eidos*, form: *Gr.*), in Mineralogy, the *Prismatic garnet*, or *grenatite* It is a silicate of alumina and lime, with the oxides of iron and manganese, and consists of four and six-sided prisms, crossing each other, at right angles. It occurs in primary rocks; and is distinguished from *garnet* by its form and the difficulty of fusing it.

STAVE, or **STAFF** (*stale: Germ.*), in Music, the five horizontal and parallel lines, on which the notes of tunes are written or printed.——A thin narrow piece of timber, of which casks are made.

STAY, in the rigging of a ship, a large strong rope employed to prevent the mast from falling aft. It reaches from the masthead forward towards the bow; and takes its name from that of the mast, as the *forestay*, *maintopmast-stay*, &c.——To *stay* means to *tack;* to be *in stays* is to be *in the act of tacking;* to *miss stays* is to *fail in tacking.*——STAY-SAIL, any sail extended on a stay.——STAY-TACKLE, a large tackle attached to the main-stay by means of a pendant, and used to hoist heavy bodies.

STEAM, water converted into a gaseous state by means of heat. When produced under the common atmospheric pressure, the elasticity of steam is equal to the pressure of the atmosphere. If the pressure under which it is generated does not exceed that of the atmosphere by more than about five pounds, it is called *low pressure* steam; otherwise it is *high pressure* steam. It has been ascertained that the quantity of heat required to convert a given quantity of water into steam is 5½ times greater than that required to raise it from the freezing to the boiling point; and hence, if the water were not evaporated, its temperature would be raised 990° above 212°; but a fluid exposed in an open vessel to the action of fire, however great the heat applied, cannot be made to indicate a higher temperature than that at the boiling point. Steam will be evolved in greater or less quantities, according to the quantity of heat applied; but the temperature will continue at exactly the boiling point. When water, exposed to the pressure of the atmosphere, is heated to the temperature of 212°, globules of steam are formed at the bottom of the vessel, and rising through the fluid may be collected at its surface. Steam is transparent, and consequently invisible; but when it has been deprived of a part of its heat, by coming in contact with cold air, it condenses and becomes water, in the form of very minute particles, which float in the air, and form a cloud. If the pressure on the fluid be increased by closing the vessel, its temperature must become higher before the elasticity of the vapour which is generated will be able to overcome the increased pressure, so as to rise from the fluid. If the pressure is increased to the amount of an additional atmosphere, that is, by about 14lbs., it will be found that the temperature of the fluid will have risen to 250° before any vapour will be given off; and these variously increased pressures will require corresponding augmentations of temperature. But increasing the temperature and elasticity of the steam does not in the least increase its mechanical effect. A cubic inch of water, changed into steam, at 212°, will occupy 1700 cubic inches. If, however, the steam is produced under a pressure of *two* atmospheres, the cubic inch of water will form only *half* as much steam, or 850 cubic inches; if under a pressure of *three* atmospheres, only *one-third* as much steam, or 561 cubic inches; and so on. The mechanical effect producible by a given quantity of water is in all cases the same; for, let us suppose the steam generated from a cubic inch of that fluid, under the ordinary atmospheric pressure, to move a counterpoised piston, that is, one practically without weight, twelve inches, the atmospheric pressure has been overcome through that distance; that is, a force of about 2080lbs. has been exerted through a space of twelve inches. But, let the cubic inch of water be changed into steam, under the pressure of two atmospheres, the piston will now be raised through only six inches; but besides overcoming the force of the atmosphere to the amount of 2080lbs. through that distance, it will also be able to raise 2080lbs.; that is, the steam in this case will move twice 2080lbs, or 4160lbs through six inches; and, according to the ordinary mechanical laws, 2080lbs. moved through twelve inches is identical in mechanical effect with 4160lbs. moved through six inches. [See MOMENTUM.] Again, let the steam from one cubic inch of water be generated under the pressure of *three* atmospheres, the piston will now be raised through only four inches; but it will be moved with a force of three times 2080lbs. or 6240lbs. but 2080lbs. moved through twelve inches, 4160lbs. moved through six inches, and 6240lbs. moved through four inches, are all equal in effect, because they produce equal momenta. Thus, just so much as we increase the pressure under which the steam is generated we increase its elasticity; but, to the same extent, we diminish the space through which it acts. And we make no alteration in the quantity of fuel consumed; for the quantity of heat communicated to the given quantity of water is the same in all cases. Hence, so far as consumption of fuel is concerned, it is a matter of indifference whether we use a high or a low pressure engine; the former occupies less space, but there is a greater waste, from the greater tendency of high pressure steam to leak, and from the increased radiation of heat, at the higher temperature. The very important facts just enumerated may be easily proved. Let a given quantity of water be changed into steam, at any pressure; five and a half times as much water, at 32°, will exactly condense it, and with the condensed steam will form six and a half times as much water at 212°. If the steam is at 212°, the temperature undergoes no change; and the ice-cold water, which will have been raised, during condensation, to 212°, will owe its elevated temperature entirely to the heat which was *latent* in the steam. It is worth remarking that, while the steam from a tea kettle will scald the hand, if held within it, that which escapes from a high pressure boiler will feel cool. This, however, is easily explained, by the fact that the steam expands when it is relieved from pressure, and the greater its elasticity the greater will be its expansion, in reality it expands to a bulk greater than it would have occupied had it been generated at a temperature of 212°, just as a spring, when drawn out of its natural position, will, on being released, not only regain its former shape, but will vibrate in the opposite direction.

STEAM BOILER, a vessel used to generate steam for the supply of a steam engine, &c. The common *tea kettle* exemplifies the simplest form of boiler; when it is used, no economy of fuel is attempted, and the heat is applied without any reference to the production of its maximum effect; cold air circulates round the kettle, and retards the heating of the water, and much heat from the fire escapes into the apartment. A better application of heat is shown in the *boiler of a laundry;* both boiler and fire are enclosed in a non conducting material; the heated air circulates more or less round the fluid, and the intensity of the fire is increased by the air which supports combustion being made to pass through the fuel, and with considerable velocity, as no other air is allowed to pass into the chimney. The old *waggon steam boiler* may be considered as the next stage of improvement; with it the smoke and heated air, in passing from the fuel to the chimney, circulated round the water to be heated, since it passed round the outer sides of the boiler. This form of boiler was, however, from its shape, extremely weak; it was applicable, with any degree of safety, to the production of only very low pressure steam; and it has been superseded by the cylindrical boiler with hemispherical heads, set in such a way as that the smoke and heated air pass round it before reaching the flue. The next step in improvement consisted in the adoption of a cylindrical boiler, having within it a smaller cylinder of equal length, through which the smoke and heated air, after circulating round the outside, passed to the chimney. The inner cylinder is placed near the bottom of the outer, that the heated air, &c. within it may not only pass through the water and be always covered by it, but may be immersed in the coldest part of that fluid which, on account of its greater density, is always found in the lowest place. The furnace is very generally situated within one end of the inner cylinder; and thus the burning fuel is surrounded on all sides by the water to be heated The heating surface is increased, and the heated gases passing to the chimney are still more effectually deprived of their heat, before escaping, by the use of two inner cylinders, instead of one; by using a number of comparatively large tubes instead of the inner cylinder—as in the marine boiler; by using a number of small tubes—as in locomotives for railways, &c. Since it is impossible to generate exactly the required amount of steam, the means of liberating any extra quantity must be provided, or the boiler will almost certainly explode; this is effected by the use of a *safety valve.* It is of a conical form, ground steam tight into a conical seat, and is loaded with a weight, depending on the number of square inches in its surface, and on the steam pressure which is required When the steam within the boiler exceeds this pressure it lifts the safety valve and escapes. Without a safety valve safety is out of the question; with a safety valve there is still danger, unless it is occasionally examined; for the valve may *adhere to its seat,* in which case the force necessary to lift it may require a steam pressure far exceeding what the boiler is able to bear. The boiler must be regularly supplied with *water* if it is inadvertently nearly or quite filled, the machinery may be injured by the introduction of water into the cylinder, or there may even be an explosion. If the supply of water is insufficient, and this is by far the most usual case, the fire or highly heated air will reach beyond the water, the boiler will then be *burned*, and therefore greatly weakened, so as not to retain strength enough to resist the ordinary pressure; or, water being thrown by the pump over the highly heated metal, a vast quantity of steam may be suddenly generated, and an explosion may occur. Two methods are used for supplying a boiler with water; one that is self-acting, and therefore the best, which consists in a cistern being placed so high above the boiler that the pressure of a column of water reaching from it to the boiler may overcome the pressure of the steam so that water may enter, when the fall of a *float* within opens a valve. But this contrivance can be used only with fixed engines, and when the low pressure steam is used; for a pressure of 15lbs. per square inch above the ordinary pressure of the atmosphere would require a column of water of about 35 feet to overcome it; a pressure of 30lbs. above that of the atmosphere would require a column of about 70 feet; but steam of from 50lbs. to 100lbs. pressure above that of the atmosphere is being often used.—*Effective pressure* is that part of the pressure which exceeds the atmospheric; it is that which is not counteracted by the pressure of the air. Steam of only about 14¾lbs. pressure to the square inch would not escape, even from an aperture in the boiler; it would be kept in by the pressure of the atmosphere; so that when steam is said to have a pressure of 15lbs. to the square inch it really has a pressure of near 30lbs., but its effective pressure is only about 15lbs., the remaining 15lbs. being neutralized by the pressure of the atmosphere. The more usual, indeed the almost universal, mode of supplying the boiler with water is by means of a *force-pump;* when water is not required, the pump is either not allowed to work, or its feed-pipe is closed by a cock—in which case the plunger works in vacuo. We must at all times be able, as it were, to look within the boiler, that we may be certain the quantity of water is neither too great nor too little. Various contrivances enable us practically to attain this object.—*Gauge-cocks* are so placed that when the boiler is properly supplied one of them, on being opened, emits water, and another steam; there is too much water if it issues from both cocks, and too little if it issues from neither. A *float*, also, is often fixed within the boiler; it is connected with a steam whistle, which sounds when the surface of the water and the float sink too low; or with a brass rod, which, passing steam-tight through a small stuffing box fixed in the top of the boiler, shows by the amount of the rod exposed to view what is the depth of water inside; the higher the surface of the water the more the rod will, of course, project. When the stuffing is not unnecessarily tightened on the rod, and the latter is kept smooth and clean, its indications will be very satisfactory. Another contrivance consists in a *glass tube*, so fixed vertically, at one end of the boiler, that the proper water level is at about half its height; and as its upper and lower ends open into the boiler, if neither is allowed to be obstructed the water will stand in it and within the boiler at the same height, and thus the water level within may be known, at any moment, by merely inspecting the tube. The matter is so important, that no *one* of these contrivances should, if possible, be relied on, and certainly no number of them, without constantly examining if they are in proper working order. All boilers, but especially marine boilers, are liable to incrustations from the substances which are generally contained in water, and are left behind when it is evaporated. These incrustations consist of substances which are bad conductors of heat, and which, therefore, not only keep the water from being heated, but allow the metal under them to have its temperature unduly raised, and therefore to be *burned.* If they happen, which is very likely, to crack from the high temperature, water rushes through the fissure; and this coming in contact with the highly-heated metal, so much steam may be suddenly generated as will cause explosion. These incrustations must, therefore, be avoided as far as possible, and, when at all considerable, must be removed; they are best prevented by frequently blowing off that part of the fluid which is most highly charged with saline substances, and which, being the heaviest, is found at the lower part of the boiler. *Hall's condenser* was proposed as a means of condensing the steam without mixture with the condensing water, that the same fluid might be used continually in the boiler, and thus incrustations be prevented; it consisted of a very extended series of pipes immersed in cold water; the principle was tried by Watt and abandoned by him, as it did not condense with sufficient rapidity, and a kind of fur collected in the pipes, which, unless frequently removed, prevented the heat of the steam from passing to the water outside. Marine boilers are rapidly corroded by the salt water which is, of necessity, used, and therefore do not last long. To secure the best effect from a boiler, the fuel should be supplied in moderate quantities at a time.

STEAM CAR'RIAGE. This name is usually applied to a locomotive which is intended for ordinary roads. Many and costly experiments have been made on this subject; but they have, as yet, produced but little result. The force required to draw a carriage on a common road is very different from that which would be sufficient on a railway; the roughness, small stones, ruts, &c., present most serious impediments, and, by the shaking they produce, greatly increase the wear and tear of a machinery, which is of necessity extremely ponderous, and extremely liable to be deranged.

STEAM-ENGINE, a machine intended for the production of motive power by means of the evaporation of water. Attempts to derive force from steam are noticed very early in the History of Science.——Hero, of Alexandria, about a century before Christ, described a contrivance, in which tubular arms, placed at right angles to an axis, were made to revolve, by the escape of steam from apertures situated at their opposite sides and ends. This, which is a most wasteful application of steam, has been re-invented at various times, and in different forms, by persons not aware of its having been previously tried, nor of the objections to which it is liable. The steam imparts motion to it on the same principle as the water to that form of turbine, known as *Barker's Mill.* [See TURBINE.] In the 17th century Branca, an Italian engineer, proposed to move a wheel by steam, blown tangentially against it. Solomon de Caus, a French engineer, raised water into a chamber, placed over a well, and communicating with it by a pipe, by filling the chamber with steam, and then condensing it; the pressure of the atmosphere on the surface of the water in the well forced it up to supply the vacuum in the chamber. With this arrangement, great quantities of steam were wasted by condensation, as long as the surface of the chamber remained cold, each time that it was filled with water, and emptied. The water was elevated from the well, not by the power of steam but by the pressure of the atmosphere; the steam being employed only to form a vacuum. The Marquis of Worcester, in his 'Century of Inventions,' describes a machine in which steam was made to raise water by pressure on its surface; but, in this case also, steam was wasted, being condensed by the cold surface of the fluid and that of the reservoir containing it. Papus proposed to generate steam in a cylinder, and, by condensing it, to move a piston, but the steam was to be generated in the cylinder itself by the application of a fire; and, therefore, the contrivance was attended with serious inconvenience. Savary, an Englishman, in 1698, patented an apparatus for lifting water by means of a vacuum produced by steam, and elevating it still higher by the pressure of steam on its surface: thus combining the methods used by De Caus and the Marquis of Worcester; and this mode of applying steam was used to a considerable extent. The next essential improvement was made by Newcomen, for which he obtained a patent in 1705. It consisted in separating the parts of the engine in which the steam was to act from those in which the water was to be raised; the weight of the atmosphere being employed for the purpose of pressure, and the steam for that of first displacing the air, and then forming a vacuum by condensation. Newcomen was thus enabled to dispense with the use of steam of great and dangerous elasticity; he worked with moderate heats, and removed at least some part of the causes of wasteful and ineffectual condensation. To him we are indebted for the introduction of the steam *cylinder* and *piston*, and for their connection with the pump by means of the main lever or *beam*, with its rods and chains: to which we might add several subordinate contrivances, which do great credit to his ingenuity. Still, however, the machine required the constant attendance of some one to open and shut the cocks at the proper intervals, for the alternate admission of steam and cold water. But a boy who was in charge of one of these engines perceived that he might cause the engine to move its own valves by connecting the cocks to the working beam. Having done this by means of strings, he left the engine to itself, and went to play. From this time to the year 1764 there seems to have been no material change in the structure of the engine, which still continued to be known by the appellation of Newcomen's, or the atmospheric engine. The boilers, however, had been removed from under the cylinder in some of the larger engines, and the cylinder had been fixed down to a solid basis. Still the steam was condensed in the cylinder; the hot water was expelled by the steam, the piston was pressed down by the weight of the atmosphere, and kept tight by being covered with water. It was moreover considered necessary that the injection cistern should be placed on high, in order that the water might enter with great force. It had been found by experience that the engine could not be loaded, with advantage, with more than seven pounds on each square inch of the piston, and the inferiority of that power to the known pressure of the atmosphere was, without due consideration, imputed wholly to friction. The bulk of water, when converted into steam, was very erroneously computed; the quantity of fuel necessary to evaporate a given quantity of water was not even guessed at; whether the heat of steam is accurately measured by its temperature was unknown; and no good experiment had been made to determine the quantity of ejection water necessary for a cylinder of given dimensions. Such was the state of matters, when, fortunately for science and the arts, Watt, then a mathematical instrument maker at Glasgow, undertook to repair the model of a steam-engine belonging to the university. In the course of his experiments with it he found the quantity of fuel and injection water it required much greater in proportion than they were said to be in large engines; and it soon occurred to him that this must be owing to the cylinder of this small model exposing a greater surface, in proportion to its contents, than larger cylinders did. This he endeavoured to remedy, by making his cylinders and pistons of substances which conducted heat slowly. He employed wood prepared on purpose, and resorted to other expedients without producing the desired effect in any remarkable degree. He found also, that all attempts to produce a greater degree of exhaustion, or a more perfect vacuum, occasioned a disproportionate expenditure of steam. In reflecting upon the causes of these phenomena, the recent discovery, that water boiled in an exhausted receiver at low degrees of heat (certainly not exceeding 100° of Fahrenheit, but pro bably, when the vacuum was perfect, much lower), occurred to him, and he immediately concluded that, to obtain any considerable degree of exhaustion, the cylinder and its contents must be cooled down to 100° at least; in which case, the reproduction of steam in the same cylinder must be accompanied with a great expense of heat, and consequently of fuel. He next endeavoured to ascertain the temperature at which water boils, when placed under various pressures; and not having any apparatus at hand by which he could make his experiments under a pressure less than that of the atmosphere, he began by trying the temperature of water boiling under great pressures; and by laying down a curve, of which the *abscissæ* represented the temperatures, and the *ordinates* the pressures, he found the law by which the two are connected, whether the pressure be increased or diminished. By a very simple experiment with a Florence flask, he ascertained that water, when converted into steam under the ordinary pressure of the atmosphere, occupies about eighteen hundred times its original space. These points being determined, he constructed a boiler in such a manner as to show by inspection, with tolerable accuracy, the quantity of water evaporated in any given time; and he also ascertained, by experiment, the quantity of coals necessary to evaporate a given quantity of water. He now applied his boiler to the working model before mentioned; when it appeared, that the quantity of steam expended at every stroke exceeded many times what was sufficient to fill the cylinder; and deducing from thence the quantity of water required to form as much steam as would supply each stroke of the engine, he proceeded to examine how much cold water was used for injection, and what heat it gained; which, to his very great surprise, he found to be many times the number of degrees which could have been communicated to it by a quantity of boiling water equal to that of which the steam was composed. Suspecting, however, that there might be some fallacy in these deductions, he made a direct experiment to ascertain the degree of heat communicated by steam to water; when it clearly appeared, that one part of water, in the form of steam, at 212°, had communicated about 140° of heat to six parts of water. The causes of the defects of Newcomen's engines were now evident. It appeared that the steam could not be condensed so as to form an approximation to a vacuum, unless the cylinder, and the water it contained, were cooled down to less than 100°; and that, at greater degrees of heat, the water in the cylinder must produce steam, which would in part resist the pressure of the atmosphere. On the other hand, when greater degrees of exhaustion were attempted, the quantities of injection water required to be increased in a very great ratio; and this was followed by a proportionate destruction of steam on refilling the cylinder. Watt now perceived, that to make an engine in which the destruction of steam should be the least possible, and the vacuum the most perfect, it was necessary that the cylinder should condense no steam on filling it; and that, when condensed, the water, forming the steam, should be cooled down to 100°, or lower. In reflecting on this desideratum, he was not long in finding that the cylinder must be preserved always as hot as the steam which enters it; and that, by opening a communication between this hot cylinder when filled with steam, and another vessel exhausted of air, the steam, being an elastic fluid, would rush into it, until an equilibrium was established between the two vessels; and that if cold water, in sufficient quantity, were ejected into the second vessel, all the steam it contained would be reduced to water, and no more steam would enter until the whole was condensed. But a difficulty arose—how was this condensed steam and water to be got out of the second vessel without letting in the air? Two methods presented themselves. One was, to join to this second vessel, which he called the *condenser*, a pipe, which should extend downwards more than 34 feet perpendicular, so that the column of water contained in it, exceeding the weight of the atmosphere, would run out by its own gravity, and leave the condenser in a state of exhaustion, except in so far as the air, which might enter with the steam and injection water, should tend to render the exhaustion less perfect: and to extract the air by means of a pump. The second method was to extract both air and water by means of a pump or pumps; which would possess the advantage over the other of being applicable in all situations. This latter contrivance was therefore preferred; and is known by the common name of the *air pump*. There still remained some defects in Newcomen's cylinder. The piston was kept tight by water; much of which passing by the sides, injured the vacuum below by its evaporation; and this water, as well as the atmosphere which came into contact with the upper part of the piston and sides of the cylinder at every stroke, tended materially to cool that vessel. Watt removed these defects, by applying oils, wax, and fat of animals to lubricate his piston and keep it tight; he put a cover on his cylinder, with a hole in it, made air and steam-tight, for the piston-rod to pass through, and employed the elastic force of steam to press upon the piston; he also surrounded the cylinder with a case of wood, or of other non-conducting substance, which, containing steam, should keep it always of an equable temperature. In 1765, Watt executed a working model, the effect of which he found fully to answer his expectations; and the improvement of Newcomen's engine, so far as the saving of steam and fuel was concerned, was now complete In short, the principle of keeping the vessel in which the elasticity of the steam is exerted always hot, and that in which the condensation is performed always cold, is in itself perfect. For, the steam never coming in contact with any substance colder than itself until it has done its office, no part is condensed until the whole effect has been obtained in the cylinder; and when it has acted there, it is so condensed in the separate vessel that no resistance remains; accordingly, the barometer indicates a vacuum, nearly as perfect as by the exhaustion of the air-pump. In 1784, Watt obtained a patent for the *parallel motion*, which was devised for the purpose of causing the piston rod to move always parallel to itself. With Watt's *single acting* engines, in which the piston was raised by a counterpoise, and depressed by condensation of the steam beneath it, an *arched* head attached to the end of the working beam, and connected by a chain with the upper end of the piston rod, was sufficient to maintain the latter in an upright position. But with his *double acting* engine, in which the piston was raised by steam under it and a vacuum over it, and depressed by steam over it and a vacuum under it, a flexible connection between the piston rod and working beam was inadmissible; while, on the other hand, they could not be *directly* connected, as the piston rod must work steam-tight through a packing box in the corner of the cylinder, and could not accommodate itself to the curved direction followed by the end of the beam. He, at the same time, invented several other useful contrivances; and in the year following, produced his *smoke consuming* furnace, *steam gauge*, *condenser gauge*, *indicator*, *governor*, &c. Many important modifications of the steam engine have been contrived since that period, and it has been gradually brought to the extraordinary perfection which it has now reached. The principle of this wonderful machine is very simple. It is, in fact, only a pump, in which the fluid is made to impel the piston, instead of being impelled by it; that is to say, in which the fluid acts as the *power*, instead of being the *resistance*. It may be described simply as a strong barrel or cylinder, in which is a closely-fitting piston, which is driven up and down by steam admitted alternately above and below from a suitable boiler; while the end of the piston-rod, at which the whole force may be considered as concentrated, is connected in any convenient way with the work that is to be performed. The power of the engine is of course proportioned to the size or area of the piston, and the force with which the steam acts. In some of the Cornish mines there are cylinders and pistons of more than ninety inches in diameter, on which the pressure of the steam equals the efforts of 600 horses; and engines constructed for many of the enormous vessels which are used at present are of even greater power. Engines are usually divided into *high* and *low* pressure, or more accurately, into *condensing* and *non-condensing*. With a condensing engine, as we have seen, the steam is condensed, by which means not only the *effective* but the total steam pressure [see BOILER] is rendered available; that is, theoretically there is a gain of about 15lbs. to the square inch, which with a non condensing engine is consumed in forcing the steam from the cylinder, in opposition to the pressure of the atmosphere; so that, in point of fact, a condensing engine would work with steam having a pressure less than that of the atmosphere; in which case the boiler would have a tendency rather to *collapse* from external than to *explode* from internal pressure. This a great economy of power; but serious deductions must be made on account of the more or less imperfect condensation, the force expended in working the air pump, and the pump connected with the condenser, &c. Besides, the non-condensing engine is so simple, so convenient, and so easily applied in almost any circumstances, that its use has become very general, and it is employed exclusively on railways. It occupies less room, requires less fuel, than a condensing engine. What appears to be, and is often considered but one engine, may really consist of two—thus a locomotive engine. Whenever it is impossible to use a flywheel, to carry the cranks over the dead points, or to render the power uniform, as on railways and in steam-vessels, two engines are so combined that when one produces its maximum the other produces its minimum effect, and the combined effect of both is practically a constant quantity; which is accomplished by fixing the cranks at right angles, on the same *axle* or *shaft*. Another very effective means of saving power consists in using the steam *expansively*, that is, cutting it off before the piston has reached the end of the cylinder, and allowing the expansion of the steam, which is retained within the cylinder, to finish the stroke; all the effect produced, after the steam is cut off, is evidently so much power gained. To illustrate this, let us suppose the pressure to be 60lbs. the square inch, the cylinder to be two feet long, and the steam to be cut off at half stroke. When the steam begins to expand in the cylinder it has a pressure of 60lbs.; when the piston has finished the stroke, the same steam, having now filled the cylinder, occupies double the space; its pressure is therefore only one-half, or 30lbs., and its average pressure, while the piston was traversing the last half of the cylinder, was $\frac{60 + 30}{2}$, or 45lbs.; hence the work done before the steam was cut off was to the work done after it was cut off, and therefore by the mere expansion of the steam, as 60 to 45, that is, as 4 to 3. It would be found that the sooner the steam is cut off the more power is gained by expansion; but if it is cut off too soon there will be an inconvenient difference in the pressures, at different parts of the stroke, and therefore the power of the engine will be subjected to too great variations. To describe the various applications of steam power would far exceed our limits; but, if we except its adaptation to the motion of carriages, perhaps few of its effects are more astounding than those perceived in the manufacture of iron. Here its resistless power is seen, when with mechanic claws it seizes masses of iron, and in a few minutes delivers them out again pressed into thin sheets, or cut into bars and ribbons, as if the metal had become soft, like clay in the hands of the potter. Well, indeed, may it be said, that, 'the steam-engine has infinitely increased the mass of human comforts, and rendered cheap and accessible all over the world the materials of wealth and prosperity. It has armed the feeble hand of man with a force to which no limits can be assigned; completed the dominion of mind over the most refractory qualities of matter; and laid a sure foundation for all those future miracles of mechanical power which are to add to and reward the labours of after generations. Already it has become alike stupendous for its force and its flexibility. The trunk of an elephant that can pick up a pin, or rend an oak, is nothing to it. It can engrave a seal, and crush masses of obdurate materials, draw out, without breaking, a thread as fine as gossamer, and lift a ship of war like a bauble in the air. It can embroider muslin and forge anchors, cut steel into ribbons, and impel loaded vessels against the fury of the winds and the waves.' A few years ago Mr. Fairbairn calculated that there was in the British Islands, or afloat, a total steam power equivalent to eleven millions of horses working; viz. in mining and the manufacture of metal, 450,000; in manufactures, 1,350,000; in steam navigation, 850,000; and in locomotives on land, 1,000,000.

STEAM-GUN, a contrivance for projecting the balls or other missiles used in warlike operations, by the expansive force of steam. The invention is chiefly due to Perkins, who is known for many useful contrivances; but it has never been submitted to the test of experience in actual warfare. As early as 1805, the French general Chasseloup is said to have shown the possibility of preparing steam artillery. In 1814, a French engineer constructed ordnance of this sort: the generator furnishing steam for six pieces of artillery, while the turning of a cock supplied all the pieces at once with the balls and steam; this machine could make 150 discharges in a minute.

STEAM NAVIGATION, is the application of the steam engine to the propulsion of vessels. The mechanism, to which the power of the steam is applied, may be either *paddle-wheels* or *screw propeller;* the former being merely an undershot water wheel, which, instead of driving the machinery is driven by it [see PADDLE-WHEEL], and the latter a screw which draws the vessel through the water [see SCREW PROPELLER], as the water against which the *paddles,* or the *blades,* act affords only an imperfect resistance. Not only is the vessel moved forwards, but some of the power is expended in moving the water backwards. In 1543, Blasco Garay exhibited to Charles V. a vessel moved by paddle-wheels driven by steam; but the way in which the motion was produced by the steam is not known. Since the year 1618 various contrivances have been proposed in England for the propulsion of vessels by steam. After several preliminary experiments, a vessel driven by steam was tried on the Forth and Clyde Canal, in 1789, by Miller, and it attained a velocity of nearly seven miles an hour. In 1801, a steam-engine, constructed on Watt's principles, was applied to a vessel constructed for the Forth and Clyde Canal Company; but the project was abandoned, in consequence of the fear entertained that the banks of the canal would be injured. The vessel which had been constructed was visited by Fulton, an American, and put into operation at his request; after which he caused an engine to be made by Bolton and Watt, for a vessel in America, which was to be propelled with paddle-wheels like that which he had seen in Scotland. This experiment was so successful that it was followed, in America, by the construction of many similar vessels. In 1812, the first steamboat used in Europe for commercial purposes was built on the Clyde, and this also was followed by many others. Steam vessels were soon afterwards used at sea; and regular lines were established between Greenock and Belfast, Dublin and Holyhead, Dover and Calais, &c. At length steam was applied to ships traversing the ocean, and it is now used in voyages to all parts of the world. Wheels having *feathering* paddles have sometimes been employed, but they are more complicated and liable to accidents; and, with a given amount of fuel, they do not seem to produce a greater effect than the ordinary kind. Some of the steamers now in common use have engines of nominally 1200 horse power; and, as they work not 8, but 24 hours a day, they are really equivalent to 3600 horses. But they are far exceeded by those of the *Great Eastern*, the largest vessel ever yet constructed. Her length is 695 feet, her depth nearly 60 feet; her paddle-wheels are 56 feet in diameter, her screw propeller 24 feet in diameter, and its shaft 164 feet in length. Her paddle-wheels are driven by four oscillating cylinders, each 74 inches in diameter and 14 feet stroke. Her screw is driven by four cylinders, each 84 inches in diameter and 4 feet stroke, and a single casting weighing 34 tons; her screw and paddle engines, taken together, are estimated at 12,000 horse power. There are 7000 tons of iron in her hull, 10,000 iron plates, and 2,000,000 of rivets. She has 6 masts and 5 funnels, with a fleet of boats. Her crew is about 400, and she can accommodate 4000 passengers. She uses 9 tons of coal per hour. When loaded she will weigh about 30,000 tons. The iron-cased frigates, some of which have been already completed, are of vast size. The *Warrior* is upwards of 400 feet in length, and 6000 tons tonnage. She is of iron, from 5 feet below the water line to the level of her upper deck she is fortified by armour plates 4½ inches thick, bolted on blocks of teak 18 inches thick, inside of which are the ordinary casing plates of the ship, ⅝ of an inch thick. Her main and upper decks are wood lined with iron. To improve her sea-going qualities her armour extends only for 300 feet amidships, her extremities being constructed in the ordinary way, her bows being made of great strength, to enable her to run into another ship. And to protect her from a raking fire, she has bulkheads fore and aft, fortified with armour like her sides. Her iron sternpost weighs 42 tons, and is the largest forging ever made. She cost 250,000*l.*

STEAR'IC ACID (*stear*, fat: *Gr.*), in Chemistry, a solid substance with acid properties, obtained by the saponification of *stearine*, one of the proximate principles of fats. Stearine may be obtained from mutton fat by melting it and mixing it with ether. When the whole has cooled, stearine crystallizes out. If the stearine be boiled with a strong solution of caustic potash a soap is formed, and when this is decomposed by an acid, stearic acid and glycerine are obtained. For commercial purposes, stearic acid is obtained by a different process, which need not here be detailed. Stearic acid is insipid and inodorous; after having been melted by heat it solidifies at 158° Fahr. into white brilliant needles grouped together It is insoluble in water, but dissolves in all proportions in boiling anhydrous alcohol; kindled in the open air it burns like wax. In the manufacture of candles it is melted in a silver pan, because other metals would colour it; when at a proper temperature it is poured into the moulds, and forms a candle closely resembling one made with wax. If the temperature, during fusion, is raised too high, the acid crystallizes, and becomes brittle; two qualities by which it is rendered nearly unsaleable, but which may be prevented by the addition of a little wax, magnesia, or French chalk.

STE'ATITE (*stear*, tallow: *Gr*), SOAPSTONE [which see] It is used in the manufacture of porcelain; also for taking greasy spots out of silk and woollen stuffs; and it is employed in polishing gypsum, serpentine, and marble

STEEL, a compound of iron and carbon in various proportions, that used for ordinary purposes seldom containing more than two per cent of carbon Steel should be manufactured from the purest iron. One process for making it is that termed *Cementation*, which consists in filling a suitable furnace with boxes containing alternate strata of malleable iron bars, and powdered charcoal, and keeping the whole for several days at a red heat, the atmospheric air being excluded During this process the texture of the iron, which was fibrous, becomes *granular*, and its surface assumes a blistered appearance: the product being hence termed *blistered steel.* Several bars of the latter being welded together, and the process being repeated, *shear steel* is the result; this being broken in pieces, and melted in a crucible, forms *cast steel*, which possesses equality of texture and a capability of being rendered extremely hard, as well as of taking a fine polish. *Natural*, or *German steel*, is produced directly from the pig iron, and afterwards refined; it is consumed largely in Germany and Austria, and is exported in great quantities to different parts of America. In this country steel has been very successfully manufactured from crude iron, which contains a much greater proportion of carbon than steel. The Bessemer process consists in blowing atmospheric air into the melted pig iron in the converting vessel, and this operation is continued until the oxygen has effected a combination with all the carbon, except the quantity required to form steel. It has also been manufactured in such a way that the bars contain cores of iron; this gives all the hardness of steel, and the tenacity of iron; and prevents articles made of it from breaking off short, as they frequently do, when formed only of hardened steel. The property on account of which steel is so valuable consists in its being rendered extremely hard by being heated to redness, and quenched in water, and in this hardness being capable of modifications by tempering, so as to be accompanied, when necessary, with great tenacity and elasticity. *Tempering* consists in reheating the steel to a temperature which depends on the degree of hardness and other qualities that are to be possessed by the article; and indicated by the colour given to a polished portion of it. When this colour is reached the steel is immediately plunged into water, to prevent any further rise in temperature. Pale straw colour indicates great hardness; a deep blue, great softness; and the intermediate shades, various degrees of hardness. A number of other metals have been combined with steel, giving rise to *silver steel*, &c.; but good common steel seems equal to any of these combinations. Steel may be made three hundred times dearer than standard gold, weight for weight.

STEEL'YARD, or ROMAN BALANCE, in Mechanics, a balance by which the gravities of different bodies are found, with the assistance of a single weight It consists of a rod or bar marked with notches, designating the number of pounds and ounces, and a weight which is movable along this bar, and is made to balance the body to be weighed, by removal to a proper distance from the fulcrum. This forms a lever of the first order.

STEER'AGE, in a ship of war, an apartment before the bulk-head of the great cabin, where the steersman stands Also an apartment in the forepart of a ship, for passengers.——*Steerage-way*, that degree of progressive movement of a ship which renders her governable by the helm ——*Steersman*, the man at the helm, employed to regulate the ship's course

STEGNOT'ICS (*stegnōtikos*, astringent; from *stegnoo*, I check bleeding: *Gr.*), medicines proper to stop the orifices of the vessels of the body, when relaxed or lacerated.

STELE, or STELA (*Gr.*), a pillar or upright stone tablet erected by the Greeks and Romans to mark a boundary, or as a memorial of some event. Stelæ came to signify monuments over the dead, whether they consisted of a single stone or were of a more elaborate nature. [See CIPPUS.]

STEL'ECHITE, a fine kind of *storax.*

STEL'LATE (*stellatus*, relating to a star: *Lat.*), in Natural History, an epithet given to anything that has parts radiating from a centre.

STEM, in Botany, that part of a plan which sustains the leaves and flower. The main stock, which supports the branches.——*Stem*, in Ship-building, the circular piece of timber into which the two sides of the ship are united at the fore-end; the fore part of the ship, as opposed to the stern.——*From stem to stern*, from one end of the ship to the other.

STEM'PLES, in Mining, cross bars of wood in the shafts of a mine.

STEN'CILLING, a method of painting on walls with a stencil, so as to imitate the figures on paper hangings.

STENOG'RAPHY (*stenos*, scanty; and *grapho*, I write: *Gr.*), the art of writing in short-hand, by using abbreviations or characters for whole words.

STENTO'RIAN (from *Stentor*, a herald, in Homer, whose voice was as loud as those of fifty men), able to utter a very loud sound.

STEPPE, a word probably of Tartar origin, used in Physical Geography to signify a level waste, destitute of trees. There are extensive steppes in the Russian empire.

STE'REOCHROME (*stereos*, solid; *chroma*, pigment: *Gr.*), a process of painting on walls, using WATER-GLASS as a means of fixing the colours in the plaster. This process has several advantages over fresco, since damp and atmospheric influences do not injure pictures in stereochrome, whilst the painting admits of being retouched, and joinings may be dispensed with. Stereochrome has been adopted on a large scale by Kaulbach in decorating the internal walls of the New Museum at Berlin, and it has been lately used in some of the wall painting in our houses of parliament.

STEREO'GRAPHY (*stereos*, solid; and *grapho*, I write: *Gr.*), the art of drawing the figures of solids upon a plane.

STEREOM'ETRY (*stereos*, solid; and *metreo*, I measure: *Gr.*), that part of Geometry which teaches the art of measuring solids or ascertaining the solid contents of bodies.

STER'EOSCOPE (*stereos*, solid; and *scopeo*, I examine; *Gr.*). No picture can give an exact representation of a solid: for the eyes, to a certain extent, look *round* the solid body, each of them seeing more of one side than of the other: and the two pictures in the eyes not being absolutely the same. This may be easily proved, by placing a small cylinder of any kind on a table, and marking by dots, &c., the width of the part seen by each eye, when the other is closed, the head being kept in the same position. The stereoscope has been invented to meet this peculiarity of vision. The most common form of instrument consists of a small box, in the back of which is placed an oblong slide, containing two photographic pictures of the same object, taken in two slightly different positions of the camera obscura [see PHOTOGRAPHY]. These pictures are both seen at once, each by the eye which corresponds to it, by means of two small tubes, containing lenses adjusted to the circumstances of, and the distance between the eyes of the observer. The result is, that the eyes combine the two pictures, and the object appears to stand out in relief, in other words to possess solidity; they are viewed by transmitted light if they are transparent, and by reflected light if opaque. [See PSEUDOSCOPE.]

STEREOT'OMY (*stereos*, solid; and *tomē*, a cutting: *Gr.*), the science or art of cutting solids into certain figures or sections; as walls or other members in the profiles of architecture.

STE'REOTYPE (*stereos*, solid; and *tupos*, a copy: *Gr.*), an entire solid plate or piece of type, cast from an impression in plaster of a page composed with moveable types. The advantage of *stereotyping* a book consists in being able, at a trifling expense, to print copies as they are required by the public. If this plan be not adopted, either a large number of copies must be thrown off at first, and these may not be called for, or the book must be retained in type, or all the expense of setting up the type, correcting the press, &c., must be again incurred whenever the number originally printed has been disposed of. Stereotypes are easily made, and impressions are taken from them with great facility. Alterations may, if required, be made in them; but it is not desirable to stereotype a work likely to be much altered. When a work is once thoroughly corrected, the stereotyping it secures accuracy.

STER'LING, in English Commerce, a term which is applied to money; signifying that it is of the fixed, or standard, national value; thus, 'a pound sterling' is not indefinitely 'a pound,' but 'an English pound.' Camden appears to offer the true etymology of this word, when he derives it from *easterling*, and corroborates, if not demonstrates, the propriety of this suggestion, by quoting old deeds, where English coin is always called *nummi easterlingi*. In explanation, he observes, that in the reign of Richard I. money coined in the eastern part of Germany grew to be much esteemed in England, on account of its purity; it was called *easterling* money, as all the people of those parts were called easterlings; and in consequence of the good character of their own money, some of the *easterling* coiners were invited into this kingdom, to perfect its coinage, which was thenceforward denominated *easterling*, *esterling*, *sterling*. [See EASTERLING.] During a considerable period, the only coin in England was one of about the value of a penny: whence it happens, that many ancient writers use the word *easterling* as a substantive, and synonymously with *penny*.——The word *sterling* has also a more general application. We speak of *sterling* value, *sterling* worth, or *sterling* wit; thereby meaning genuine and of good quality.

STERN, the hind part of a ship or other vessel.——*Stern-chase*, a cannon placed in a ship's stern, pointed backward, and intended to annoy a ship that is in pursuit of her.——*Stern-frame*, the several pieces of timber which form the stern of a ship.——*Stern-post*, a straight piece of timber, erected on the extremity of the keel to support the rudder, and terminate the ship behind.

STER'NUM, in Anatomy, the *os pectoris*, or breast-bone, a bone which composes the fore-part of the breast, and into which the ribs are fitted. It forms the front of the human chest from the neck to the stomach. The *sternum* is wanting in fishes, amphibians, and ophidians. In birds it is largely developed, and has a projecting-keel.

STER'TOR, a noisy kind of respiration, such as is observed in cases of apoplexy; loud snoring or snorting.

STETH'OSCOPE, in Medicine, a tubular instrument, usually of wood, for enabling the physician to hear the sounds made by the action of the heart and lungs, and thus discover the nature and seat of disease. When in use, the physician applies the stethoscope to the chest or abdomen of a patient, and places the ear to the narrow end. This useful instrument was invented by Laennec in the 18th century.

STEW'ARD. The greatest officer under the crown is the *lord high steward of England*, an officer that was anciently the inheritance of the earls of Leicester, till forfeited by Simon de Montfort to king Henry III. But the power of this officer was so great that it has not been judged safe to trust it any longer in the hands of a subject, excepting only occasionally; as to officiate at a coronation, at the arraignment of a nobleman for high treason, or on other solemn occasions. During his office, the steward bears a white staff in his hand, and on the trial, &c. being ended, he breaks the staff, and with it his commission expires. There is likewise a lord steward of the royal household, who is the chief officer of the court, &c.——In colleges, an officer who provides food for the students, and superintends the concerns of the kitchen. ——In a ship of war, an officer who is appointed by the purser to distribute provisions to the officers and crew. In other ships, a man who superintends the provisions and liquors, and supplies the table.

STHE'NIC (*sthenos*, strength: *Gr.*), in Medicine, an epithet applied to diseases in general which arise from inflammation or increased action; the opposite of *asthenic* diseases, or such as arise from debility.

STICK'LEBACK, the name given to some small freshwater fishes allied to the genus *Gasterosteus*. The commonest British species is the *G. trachurus*, whose tail is square in section. The sides are covered with large bony plates, and on the back are three sharp spines capable of elevation or depression at pleasure.

STIG'MA (a mark: *Gr.*), in Botany, that part of the pistil which receives the pollen when it issues from the anther. It is glandular, and thus detains the powder.

STIGMA'TA (marks: *Gr.*), the external pores by which air enters the tracheæ of insects.——*Stigmata*, in Antiquity, certain marks impressed on the left shoulders of the soldiers when enlisted.——*Stigmata* were also a kind of notes or abbreviations, consisting only of points disposed various ways, as in triangles, squares, crosses, &c.——In Roman Catholic Hagiography, marks of the five wounds of Christ, pretended to have been miraculously impressed on the bodies of certain saints.

STIG'MATIZING (*stigmatizo*, I brand: *Gr.*), in Antiquity, the act of affixing a mark upon slaves: sometimes as a punishment, but more usually in order that they might be recognised. It was done by applying a red-hot iron, marked with certain letters, to their foreheads, till a fair impression was made, and then pouring ink into the furrows, that the inscription might be the more conspicuous. *Stigmatizing*, among some nations, was, however, looked upon as a distinguishing mark of honour and nobility.

STIL'BITE (*stilbos*, glittering: *Gr.*), a mineral of a shining, pearly lustre, and a whitish or gray colour. It has sometimes been called *Foliated zeolite* or *Radiated zeolite*.

STILL (*stillo*, I drop: *Lat.*), a chemical apparatus for vapourising compound fluids, and re-condensing the vapours of each of the component parts as they are successively raised by heat. It consists of a body, or boiler, a worm, a refrigerator, and a receiver.

STILPNOSIDE'RITE (*stilpnos*, glittering; and *sidēros*, iron: *Gr.*), a mineral of a brownish black colour, massive, in curving concretions, splendent and resinous. It is a native oxide of iron.

STIM'ULANT (*stimulo*, I incite: *Lat.*), in Medicine, an epithet for whatever excites and increases the action of the bodily organs.——*To stimulate*, in a general sense, is to rouse or animate to action by some powerful motive. In a medical sense, to excite or increase bodily action; as to *stimulate* a torpid limb, or to *stimulate* the stomach and bowels.

STIM'ULUS (*Lat.*), any medicine or aliment which increases or excites the energy of an animal.

STING, an organ projected by many insects in defence against real or supposed dangers. In most instances, this instrument is a tube, through which a poisonous matter is discharged, which inflames the flesh, and in some instances proves fatal.

STIPEN'DIARY (*stipendiarius*; from *stipendium*, pay: *Lat.*), one who performs services for a settled compensation, or stipend, either by the day, month, or year.

STI'PES, or **STIPE** (*stipes*, the trunk of a tree: *Lat.*), in Botany, that part of a palm or a fern which bears the leaves and flowers.

STIP'ITATE (*Lat.*), in Botany, supported by or elevated on a stipe.

STIP'PLING, in the Arts, a method of engraving in dots, as distinguished from *etching* in lines. [See ENGRAVING.]

STIP'ULA, or **STIP'ULE** (*Lat.*), in Botany, a small appendage or scale at the base of nascent petioles; stipules are in pairs or solitary. Leaves that are destitute of them are said to be ex-stipulate.

STIR'RUP in Ship-building, a piece of timber put under the keel when some part of it is lost.——*Stirrups*, in a ship, short ropes, having their upper ends plaited, nailed round the yards, and with eyes in their lower ends, through which the hawsers are reeved, to keep them parallel to the yards.

STI'VER, a Dutch coin, equal to about a halfpenny in value.

STO'Æ (*stoai : Gr.*), in Antiquity, porticos in Athens, which were the resort of philosophers, particularly of the Stoics.

STOAT, Ermine weasel. [See ERMINE.]

STOCK (*stoc: Sax.*), in Commerce, any fund consisting of money or goods employed by a person in trade. It is a general name for the capitals of our trading companies. And also denotes any sum of money which has been lent to government, on condition of receiving a certain interest till the money is repaid. Hence the price of stocks, or rates per cent., are the several sums for which 100*l.* of those respective stocks sell at any given time.——*Stock*, the wooden part of many instruments, as the *stock* of an anchor, the *stock* of a gun, &c.——*Stock*, in Agriculture, the domestic animals or beasts belonging to the owner of a farm; as a *stock* of cattle or of sheep. Cattle are also called *live stock.*——*Stocks* (plur.), a machine consisting of two pieces of timber, in which the legs of criminals are confined by way of punishment.——*Stocks*, the frame or timbers on which a ship rests while building. Hence we say, 'a ship is *on the stocks*'

STOCK'-BROKER, one who deals in the purchase and sale of stocks, or shares in the public funds, for others.

STOCK'-DOVE, the *Columba œnas*, or wild pigeon of Europe, long considered as the *stock* of the domestic pigeon, but now regarded as a distinct species.

STOCK'-EXCHANGE, the place or building where the public stock is bought and sold. The *Stock-exchange*, situated in Capel-court, was opened in 1802. Formerly the place of rendezvous for persons transacting business in the stocks, was Jonathan's coffee-house, in 'Change Alley, Cornhill, and it is from this circumstance that the expression *Alley* is familiarly used, as a cant phrase for the Stock-exchange, and that a petty speculator in the funds is styled a 'dabbler in the alley.' [See EXCHANGE.]

STOCK'-JOBBER, one who makes it his business to buy and sell stocks and shares on his own account. Stockbrokers deal with him, and hence it happens that there are two prices for the same commodity in the market, one for buyers and another for sellers.——*Stock-holder*, one who is a proprietor in the public funds; or in the funds of a bank; or other company.

STOCK'INGS are made either of silk, wool, cotton, or thread, &c.; by the hand, or woven in a frame. Silk stockings were first worn by Henry II. of France, 1547. Howell says, 'that, in 1560, queen Elizabeth was presented with a pair of black silk knit stockings by her silk-woman, Mrs. Montague, and she never wore cloth ones any more.' He adds, 'that Henry VIII., that magnificent and expensive prince, wore ordinarily cloth hose, except there came from Spain, by great chance, a pair of silk stockings for gala-days.' The English and French have often contested the honour of inventing the stocking-frame; but whatever pretensions the French may suppose they have to it, this honour was certainly due to Mr. W. Lee, of Woodborough, Nottinghamshire. He attempted to set up an establishment at Calverton, near Nottingham, but instead of meeting with that success to which his genius and inventions so well entitled him, he was discouraged and discountenanced. Being, however, invited by Henry IV. of France, who promised him a magnificent reward if he would carry his machinery to that country, he settled at Rouen, where he introduced the stocking-frame with distinguished success; but after the assassination of the king, the concern got into difficulties, and Lee died in poverty at Paris. Some of the workmen who had emigrated with him returned to England, and established themselves in Nottinghamshire, which still continues the principal seat of the manufacture. During the course of the last century the machine has been very greatly improved.

STO'ICS (*stoikio : Gr.*), in Antiquity, a sect of philosophers among the Greeks, whose founder was Zeno. They denied the existence of innate ideas; and consequently held that sensation and reflection were the only foundations of human knowledge. They taught that the true end of man consists in living conformably to nature, and in obedience to his internal monitor, that particle of the divinity which constitutes the soul. They taught that good is what conducts men to felicity, and that all good things are equal; that passions arise from false judgments; that duty consists in the investigation of moral truth, and in living agreeably to the obvious destination of our nature. They had also paradoxes peculiar to themselves, asserting that pain is no evil; that a wise man is free from all perturbation of mind; and that it is the duty of man to submit without complaint to the unavoidable necessity imposed on him by his destiny. [See PHILOSOPHY.]

STO'LA (*Lat.; from stolē: stello*, I equip: *Gr.*), in Antiquity, a long robe in use among the Roman ladies, over which they wore a large mantle, or cloak, called the *pallium.*——Also a sacerdotal ornament worn by the Roman Catholic parish priests over their surplice, as a mark of superiority in their respective churches; and by other priests over the alb while celebrating mass.

STOLE, GROOM OF THE. An officer in the household of the British Sovereign. The place is a sinecure, and when a female sovereign occupies the throne, it is usually held by the mistress of the robes. The stole is a narrow vest lined with crimson silk, and formerly embroidered with roses, fleur de lis, and crowns.

STOM'ACH (*stomachos ; from stoma*, a mouth, literally an opening: *Gr.*), in Anatomy, a hollow membranous receptacle, situated in the epigastric region, immediately under the diaphragm, and obliquely between the liver and the spleen; the superior orifice of which is termed the *cardia*, and the inferior the *pylorus.* The use of the stomach is for the digestion of food; that is, to receive, contain, dissolve, and change what is swallowed; and after a sufficient concoction, to expel it through the pylorus into the intestines. It is also the organ in which the sensation of hunger resides. The stomach is largely supplied with nerves, which come from the eighth pair, and the sympathetic; like the intestines, it has three coats, connected together by cellular membrane.

STOMACH'ICS (*stomachikos*, for the stomach: *Gr.*), medicines which excite the action and strengthen the tone of the stomach.

STOM'ACH-PUMP, a small pump for removing poisons from the stomach. It resembles the common syringe, except that there are two apertures near the end, instead of one, which, owing to valves in them, that open different ways, become what are called a *sucking* and a *forcing* passage. When the object is to extract from the stomach, the pump is worked while its sucking orifice is in connection with an elastic tube passed into the stomach; and the discharged matter escapes by the forcing orifice. When it is desired, on the contrary, to inject water or other liquid into the stomach, the connection of the apertures is reversed.

STO'NE-CROP, a name given to plants of the genus *Sedum*. The stone-crop tree or shrubby glass-wort is of the genus *Chenopodium*.

STO'NE-FRUIT, a *drupe*, or kind of fruit in which the seed or kernel is enclosed in a hard case, covered with pulp; as cherries, plums, &c.

STO'NEHENGE, the remains of a structure supposed to have been erected by the ancient Britons; still extant upon Salisbury Plain, in Wiltshire. It consists of many unhewn stones, which, with some that are wanting, appear to have originally composed four ranks, one within another. Some of them, especially in the outermost and the third ranks, are twenty feet high and seven broad. The vertical stones sustain horizontal ones, laid across their heads, and fastened by mortises. The whole is supposed to have been once joined together. The purpose of a place of this description among the generations which, two thousand years ago, peopled the island of Britain, seems to have been that of religious worship. The matter has excited much discussion amongst antiquarians.

STONE. The ancients were far more careful than the moderns in selecting good materials for their public edifices; and hence, notwithstanding all the casualties to which they were exposed, such magnificent remains of them exist even at the present day. The most important building stones in Britain are, *Granites*, obtained chiefly in Cornwall, Devonshire, Leicestershire, Aberdeenshire, Wicklow, and Carlow; *Porphyries*, *Syenites*, and *Elvans*, in Cornwall, Devonshire, Leicestershire, and many parts of Scotland and Ireland; *Sandstones*, chiefly in Yorkshire, Derbyshire, Shropshire, Surrey, &c., in several parts of Scotland—the Portland and Craigleith kinds being included; *Millstone grit*, found abundantly in Derbyshire, Yorkshire, and most of the coal districts; *Dolomites* or *Magnesian limestones*, in Yorkshire, Durham, Northumberland, Derbyshire, and Nottinghamshire; *Olites*, of which bathstone is an example, and which are obtained of excellent quality in the quarries of Ancaster and Kelton; *Limestones*, which are extremely varied, and of which Purbeck marble, Derbyshire marble, Lias Devonian limestone, and mountain limestone, are examples; *Slates*, obtained abundantly in North Wales, Devonshire, Cornwall, and some parts of Scotland and Ireland.

STONE ARTIFICIAL, the invention of Mr. Ransome, is composed of sand chalk or other mineral substance intimately mixed with WATER-GLASS. When still plastic it can be pressed into blocks or moulds, or it can be rolled into slabs. It is then saturated with a solution of chloride of calcium, when a double decomposition of the two solutions employed takes place. The silica of water-glass combines with the calcium, and at once forms an insoluble silicate of lime in the pores of the new stone which firmly cements together all its particles, whilst the chlorine combines with the soda and forms common salt, which is removed by simple washing. The resulting stone is exceedingly strong and is likely to be very durable. Another method, the invention of Messrs. Bartlett, consists in employing a mixture of water-glass with a solution of aluminate of soda. The resulting silicate of alumina when dried in the pores of the stone is perfectly insoluble in water.

STO'RAX (*Lat.*), a resinous and odoriferous drug, or solid balsam; of a reddish brown colour. It is obtained from the *Styrax officinalis*, a tree which grows in Syria. It is a stimulating expectorant. *Liquid storax*, or *styrax*, is a liquid or semi-fluid balsam, obtained from the *Liquidamber stiraciflua*, a tree which grows in Virginia. Trees in other parts of the world belonging to the same genus also yield liquid storax.

STORK, the name of large grallatorial birds belonging to the genus *Ciconia*. They are nearly allied to the crane and the heron. Besides the common or white stork (*Ciconia alba*) there is another European species, viz. the black stork, with the breast and belly white, an erect and beautiful bird somewhat larger than the common heron. ——In Heraldry, the stork, as an emblem of piety and gratitude, is a frequent bearing in coat armour.

STORMS. The causes which produce storms, tempests, hurricanes, &c., are very obscure. It is difficult to arrive at general laws regarding them; since it is not easy to obtain an exact knowledge of the various circumstances which accompany them. Storms are violent and destructive in the torrid zone; they are comparatively insignificant in temperate, and are scarcely known in polar regions. It was formerly supposed that a storm was merely a wind blowing in a certain direction at the rate of 100 or 120 miles an hour; but it has been recently found to be far more complicated in its nature. There is reason to believe that, in the northern hemisphere, the great body of the storm whirls in a horizontal circuit, round a vertical or some what inclined axis of rotation which is carried forward with it; and that to a spectator placed in the centre the rotation is always from *right to left*. Storms travel in a direction differing from the actual movement of the wind at the time. When the storm progresses westward, the wind, at the commencement, is from a northern quarter, and towards the end from a southern. When the progressive motion is eastward, the phenomena are reversed; southern storms are subject to the same modifications as northern, but in a reversed order. In all latitudes, the barometer sinks during the first half of the storm, in every part of track; and rises during the second. It is asserted by some that in storms the tendency of the wind is from all round to some centre or central line, and there may be storms having this character also. Were the phenomena of storms well understood, the navigator might avoid those tracks in which they prevail at particular times; or, being caught by one, might steer the course by which he should soonest escape from it.

STO'RY-POSTS, in Carpentry, upright timbers disposed in the story of a building, for supporting the superincumbent part of the exterior wall by means of a beam over them.

STRABIS'MUS (*strabos*, oblique: *Gr.*), in Surgery, an affection of the eyes in consequence of which the optic axes cannot be both directed to the same object

STRAIT, or as it is generally written, STRAITS, in Geography, a narrow pass of the ocean, through which the water flows from one sea to another. The straits of Gibraltar, about 130 miles long and 12 broad, join the Mediterranean sea with the Atlantic ocean. The strait which joins the Baltic with the Atlantic is called the Sound; and that between Britain and France, the Straits of Dover.

STRAMO'NIUM, the *Datura Stramonium* of botanists, nat. ord. *Solanaceæ*, a plant growing wild in Europe and America. All parts of the plant exhale a strong and nauseous odour; and, taken internally, it is one of the most dangerous of narcotic poisons. It has, notwithstanding, been employed with advantage in convulsive and epileptic affections; and smoking the dried leaves has often proved beneficial in cases of asthma.

STRAPPA'DO, a Military punishment, not now used. It consisted in drawing an offender to the top of a beam, and letting him fall; by which means a limb was sometimes dislocated.

STRAT'EGY (*stratēgia*; from *stratos*, an army, and *ago*, I lead: *Gr.*), that branch of the military science which is concerned in the conducting operations in the field.

STRATIFICA'TION (*stratum*, a bed; and *facio*, I make: *Lat.*), in Mineralogy and Geology, a term signifying the process by which substances in the earth have been formed into strata or layers. Also, in Chemistry, the placing layers of different substances one upon another in a crucible.

STRATOC'RACY (*stratos*, the army; and *kratos*, power: *Gr.*), a Military government, or that form of government in which the soldiery bear the sway.

STRA'TUM (a bed: *Lat.*, plural *strata*), in Geology, a layer of rock or earth. The crust of the globe is built up of strata, into which igneous or non-stratified rocks have intruded. Stratified rocks (with the exception of those that have spread in sheets from some volcanic orifice) have been deposited by water and are turned sedimentary. The nature of their fossil contents will determinate whether the water was salt or fresh, whether the strata were spread over the bottom of an ocean, or a lake. Strata which were formed at the bottom of an estuary contain the remains of animals some of which lived in the river or on its banks, and others in the sea, into which that river debouched. The manner in which stratified deposits are thrown down may be seen whenever a lake is drained. All the streams that fed the lake brought their contributions of mud and sand, and spread them over the bottom of the lake. The mud of the Nile valley is stratified, and if a pit be dug in it, the layer of any year may be distinguished from that preceding and that following. Geologists suppose that the stratified rocks of the whole globe, which are many thousands of feet in thickness, have been similarly formed, and that they represent the accumulations of a countless series of ages, during which the different parts of the earth's crust have been again and again elevated above, and depressed below, the level of the ocean. The relative age of a stratum is determined not only by its position amongst other strata, but by the relationship of its organic remains to existing forms of life [See GEOLOGY.]

STRA'TUS (same *deriv.*), the name given by meteorologists to a widely extended continuous and horizontal sheet of cloud, increasing upwards from below. Mists ascending from valleys and sheets of water would be comprehended under this term.

STRAW'BERRY, the fruit of plants belonging to the genus *Fragaria*, nat. order *Rosaceæ*. The gardener's art has produced many varieties of this delicious fruit.

STREAM'-TIN, *Tinstone*, a native oxide of tin, found in rounded particles and masses, mixed with other alluvial matter; it furnishes the finest grain tin.

STRENGTH, in Mechanics, force or power. ——STRENGTH OF ANIMALS, the muscular force or energy which they are capable of exerting. The experiments made on this subject, by different persons, have given very different results; which is to be expected, since animal strength is liable to variations, from a great number of circumstances. The force which an animal is able to exert against an obstacle is greatest when the animal is still; when it is in motion, some of its force is employed to produce this motion. There is a velocity at which it can carry no load, and another at which it can do the maximum quantity of work. The same animal will exert very different amounts of force, with different kinds of work.——**STRENGTH OF MATERIALS**, **is the force with which a body resists an effort to** separate its particles. The strength of a body may be exerted in four ways; in resisting a force tending to tear it asunder; in resisting a force tending to break it across; in resisting compression or crushing; and in resisting a force tending to wrench it asunder by tortion.

STREPITO'SO, in Music, an Italian word denoting that the part to which it is prefixed must be performed in an impetuous and boisterous style.

STRI'Æ (*Lat.*), in Architecture, the fillets which separate the furrows or grooves of fluted columns.

STRI'ATED(*stria*, a groove: *Lat.*), in Natural History, an epithet given to anything which is marked with furrows.

STRI'DOR DEN'TIUM (*Lat.*), a grinding of the teeth.

STRIDULA'TION (*stridulus*, creaking: *Lat.*), the noise made by some insects, such as crickets and grasshoppers.

STRI'GÆ (*Lat.*), in Architecture, the flutings of a column.

STRIKE, in Geology. [See DIP.]

STRIX (*Lat.*, from *strinx*; from *strizo*, I cry shrilly: *Gr.*), in Ornithology, a genus of birds of which the owl is the type. [See OWL].

STRO'BILUS (*strobilos*, a fircone: *Gr.*), in Botany, a spike of fruit bearing scales, each of which covers one or two seeds, as amongst the coniferous order. Sometimes the scales are thin and membranous, as in the hop.

STRON'TIA, in Chemistry, an alkaline earth; it is an oxide of the metal *Strontium*, and occurs as a carbonate, in the lead mines of *Strontian* in Argyleshire; whence its name. It is a greyish-white infusible substance, having an alkaline reaction on vegetable colours, and an acrid burning taste. It heats when moistened, and slakes into a white pulverulent hydrate; its solution in hot water on cooling deposits crystals in foursided tables. Its salts give a red tinge to flame. The compounds of strontia, unlike those of baryta, are not poisonous.

STRON'TIANITE, in Mineralogy, prismatic barytes, or carbonate of strontian, a mineral that occurs massive, fibrous, stellated, and crystallized in the form of a hexahedral prism, modified on the edges, or terminated by a pyramid.

STRON'TIUM, a heavy white metal, which oxidizes in the air, and decomposes water at ordinary temperatures. Its equivalent is 43·8. It is obtained from its oxide called *Strontia*, which see.

STRO'PHE (*Gr.*, literally, a turning), in Greek poetry, a *Stanza*: the first member of a poem. This is succeeded by a similar stanza called the *antistrophe*, which see.

STRUC'TURE (*structura*; from *struo*, I erect: *Lat.*), in Mineralogy, the particular arrangement of the integrant particles or molecules of a mineral.

STRU'MA (*Lat.*), in Medicine, glandular tumours on the neck and throat indicating a scrophulous habit.

STRUT, in Architecture, a piece of timber placed obliquely from a king or queen post, to support a rafter [see ROOF]. It is also called a *brace*.

STRU'THIO (*Lat.*), in Ornithology, a genus of birds. [See OSTRICH.]

STRYCH'NIA, or **STRYCH'NINE** (*strychnos*, nightshade: *Gr.*), in Chemistry, a poisonous vegetable alkaloid, found in the seeds (*nux vomica*) of the *Strychnos Nux Vomica*, a tree belonging to the nat. ord. *Loganiaceæ*. It is in the form of white crystals, and its operation is accompanied by lockjaw and other tetanic affections.

STUC'CO (*Ital.*), in Architecture, a term applied to many calcareous cements; but usually employed to designate one consisting of fine lime and sand, used as the third coat in three-coat plaster. *Bastard stucco* contains a small quantity of hair.

STUD, in Building, a small piece of timber or joist inserted in the sills and beams, between the posts, to support the beams or other main timbers.—A collection of breeding horses and mares.

STUD'DING-SAIL, or *scudding sail*, in Navigation, a sail that is set beyond the skirts of the principal sails. The studding-sails are set only when the wind is light, and appear like wings in the yard-arms.

STUR'GEON (*sturio*: *Lat.*), a large cartilaginous fish of the genus *Accipenser*, having the body armed with rough bony tubercles, of which there are several series. The *isinglass* sturgeon grows to the length of twenty or twenty-five feet; though they are generally caught much smaller. There are four cirri at the extremity of the under jaw; the eyes are large, and stand at a great distance from the extremity of the snout. The flesh is much esteemed; from the roe is made *caviare*, and from the swim bladder isinglass. [See FISHERIES.]

STYLE, in Literature, a term used metaphorically, from the *stylus* or ancient pen, to signify the writing. *Style* is the choice and arrangement of words, or the manner in which a person expresses himself in writing. Although in a language there can be but one syntax, there may be many kinds of style, and all equally good. Swift says, 'proper words in proper places make the true definition of style.'—*Style*, in Chronology, the manner of computing time, with regard to the Julian or Gregorian calendar, and termed either *old* style or *new*. By the *old style* the year consisted of 365 days and 6 hours; but the new or Gregorian style was made to correspond more nearly with the period of the sun's revolution. [See CALENDAR.] The reformation of the style was made in 1577; but it was not adopted in Protestant countries until a considerable time after, and it has not yet been introduced into Russia or Greece. It was ordered to be used in England by statute, in 1752, being termed the *new style*; the 3rd September 1752 was reckoned the 14th; the year which hitherto began the 25th of March was thenceforward to commence the 1st January, and from the 1st January to the 24th March, which should have belonged to the end of the year 1751, was considered as the commencement of the year 1752. Thus, not only was the year 1751 made to consist of little more than nine months, but, in reality, January, February, and twenty four days of March were transferred from each year to that which had succeeded it. These changes account for the peculiar modes in which dates are sometimes given by authors of the last century. Sometimes the date is indicated to be according to the old style by O.S. Sometimes two numbers mark the date to both styles, as $\frac{19}{30}$ June 1753; or two different months, as $\frac{\text{30 June}}{\text{11 May}}$ 1758; or two different years, as $\frac{\text{23 Feb. 1753}}{\text{6 March 1754}}$.——*Style*, in Architecture, a particular mode of erecting buildings; as the *Gothic* style, the *Saxon* style, the *Norman* style, &c.——In Botany, the middle portion of the pistil, connecting the stigma with the ovary. They are of various shapes.

STYLI'TES (*stulos*, a pillar: *Gr.*), in Ecclesiastical History, a sect of solitaries, or fanatics, in the East, who performed a kind of penance by dwelling on columns or pillars; one of them, termed *Simeon Stylites*, is said to have lived thirty-seven years on several of various heights, the last he used being of very considerable elevation.

STYLO, in Composition, is applied to those muscles which are attached to the *styloid process* of the temporal bone; thus the *styloglossus*, which moves the tongue, &c.

STY'LOID (*stulos*, a writing pen; and *eidos*, form: *Gr.*), having some resemblance to a *stylus*, or pen; as the *styloid* process of the temporal bone.

STYP'TICS, medicines which have the property of stopping hemorrhage, or discharges of blood. The word *styptic*, though signifying nearly the same as *astringent*, is used in a different and more limited sense; *astringents* usually denoting internal applications for stopping bleeding, or for strengthening the solids; *styptics*, external applications for restraining discharges of blood.

STY'RAX (*Gr.*), in Botany, a genus of plants, nat. ord. *Styracaceæ*. The species are two, growing in warm climates, several of which yield the gum resin called STORAX.

SUB, a Latin preposition for *under* or *below*. It is used as a prefix to many English words, and denotes inferiority of rank or defect in quality; as subaltern, subordinate, &c. It is prefixed to words in a scientific description of a plant or animal to signify nearly but not quite.

SU'BAH, in India, a province or viceroyship. Hence *subahdar*, the governor of a province. *Subahdar* is also used for a native of India, who ranks as captain in the European companies.

SUB'ALTERN (*subalterne: Fr.*), a term for a military officer below the rank of captain.

SUBCLA'VIAN (*sub*, under; *clavicula*, the clavicle: *Lat.*), in Anatomy, an epithet applied to anything under the arm-pit or shoulder, whether artery, nerve, vein, or muscle.

SUBCON'TRARY, in Geometry, a term used when two similar triangles are so placed as to have a common angle at their vertex, and yet their bases not parallel.

SUBCOR'DATE (*sub*, slightly; *cor*, the heart: *Lat.*), in Botany, somewhat similar to a heart in shape.

SUBCOS'TAL (*sub*, under; *costa*, a rib: *Lat.*), in Anatomy, a term for the internal intercostal muscles.

SUBCUTIC'ULAR (*sub*, under; *cutes*, the skin: *Lat.*), in Anatomy, being under the cuticle or scarf-skin.

SUB-DOM'INANT, in Music, the fourth [illegible] above the tonic, being under the dominant.

SUB'EROSE (*suber*, cork: *Lat.*), in Botany, having the appearance of being gnawed or a little eaten.

SU'BEROUS (same *deriv.*), soft and elastic, like cork.

SUBJUNC'TIVE MOOD (*subjunctivus*, relating to binding together: *Lat.*), in Grammar, a form of the verb which mentions a thing *conditionally* or by way of *supposition;* and is denoted in the English language by the addition of *if*, *though*, or some other conjunction, expressed or understood.

SUBLAPSA'RIAN, in Theology, one who maintains that God *permitted* the fall of Adam without positively predetermining it; a doctrine which is in opposition to the *supralapsarian* of high Calvinism.

SUB'LIMATE, in Chemistry, any substance procured by the process of sublimation.

SUB'LIMATION, an operation by which solids are changed by heat into vapour, and then condensed into a solid form again; it differs from distillation, in which the vapour is condensed into a liquid. This process is often used to purify or separate substances. When the crystals obtained by sublimation are extremely minute, so as to present the appearance of a powder, they are sometimes termed *flowers:* thus flowers of sulphur.

SUB'LIME (*sublimis: Lat.*), an abstract quality which like Beauty is not capable of precise definition. Whilst a beautiful object pleases and delights us a sublime one astonishes, and the sensations excited by a grand object seem to stand between those caused by the other two. The Material sublime is excited by the vastness of some object in nature; such as a range of lofty mountains. The Spiritual sublime projects our thoughts at one stroke into the illimitable. The material works of man may be grand, but are seldom if ever sublime, except in so far as they act in raising in us the sense of spiritual sublimity.

SUBLIME PORTE, the state ministry and council of the Turkish Sultan. The grand vizir is president, and under him are the minister for home affairs, the minister for foreign affairs (the Reis Effendi), and the minister of the executive power.

SUBLIN'GUAL (*sub*, under; and *lingua*, the tongue: *Lat.*), in Anatomy, situated under the tongue; as the *sublingual glands*, which secrete the saliva.

SUBLUXA'TION (*sub*, in some degree; and *luxatus*, a dislocation: *Lat.*), in Surgery, a violent sprain or incomplete dislocation.

SUBMARI'NE (*sub*, under; and *mare*, the sea: *Lat.*), an epithet for what exists or happens under the sea or water; as a *submarine* explosion, or *submarine* telegraph, &c.

SUBMAX'ILLARY (*sub*, under; and *maxilla*, the jaw: *Lat.*), in Anatomy, an epithet for two salivary glands, situated immediately within the right and left angles of the lower jaw.

SUBME'DIANT, in Music, the sixth note, or middle note between the tonic and subdominant descending.

SUBMUL'TIPLE, in Arithmetic, a number or quantity contained in another number or quantity a certain number of times: as 4, which is the submultiple of 24, being contained in it six times.

SUBNU'DE (*sub*, in some degree; and *nudus*, naked: *Lat.*), in Botany, an epithet for a plant almost naked or bare of leaves.

SUBOCCIP'ITAL (*sub*, under; and *occiput*, the back part of the head: *Lat.*), in Anatomy, under the occiput; as, the *suboccipital nerves*.

SUBORNA'TION (*suborno*, I suborn: *Lat.*), in Law, the crime of procuring a person to take such a false oath as constitutes perjury.

SUBPŒ'NA (under the penalty: *Lat.*), in Law, a writ commanding the attendance in court of the person on whom it is served. —*Subpœna ad testificandum*, compels to attend and give evidence.——*Subpœna duces tecum* compels to bring a written document for the purpose of producing it at the trial.

SUBREP'TION (*subripio*, I take away privily: *Lat.*), the act of obtaining a favour by surprise or unfair representation, that is, by the suppression of facts.

SUBROGA'TION (*subrogo*, I substitute: *Lat.*), in the Civil Law, the substituting of one person in the place of another, and giving him his rights.

SUB'SALT, in Chemistry, a salt with less acid than is sufficient to neutralise its radicals.

SUBSCAP'ULAR (*sub*, underneath; and *scapula*, the shoulder blade: *Lat.*), in Anatomy, beneath the scapula.——The *subscapular artery* is the large branch of the axillary artery which rises near the lowest margin of the scapula.

SUBSCRIP'TION (*subscriptio*; from *subscribo*, I write underneath: *Lat.*), the act of signing or setting one's hand to a paper. The word is frequently employed with reference to the oaths and test articles which persons are compelled to take and subscribe on admission to membership in a university, or into the established church, or to an office under government.

SUB'SIDY (*subsidium*: *Lat.*), an aid or tax granted to the king, by parliament, upon any urgent occasion, and levied according to a certain rate on lands and goods; but, in some of our statutes, it is confounded with *customs*. It sometimes signifies, in modern usage, a sum of money given by the government of one nation to that of another, for the immediate purpose of serving the latter, and the ultimate one of benefiting the former. Thus Great Britain *subsidised* Austria and Prussia, to engage those powers in resisting the progress of the French in the time of the first Napoleon. It is also employed with reference to a payment of public money to a company towards the support of a line of steamers, or of a theatre, as in France.

SUB'SOIL, the bed or stratum of earth which lies beneath the surface-soil: the *substratum*.

SUB'STANCE (*substantia*: *Lat.*), something that we conceive to subsist of itself, independently of any created being, or any particular mode or accident. Our ideas of substance, as Locke observes, are only such combinations of simple ideas as are taken to represent distinct things subsisting by themselves, in which the confused idea of substance is always the chief. Thus the combination of the ideas of a certain figure, with the powers of motion, thought, and reasoning joined to the substance, make the ordinary idea of a man; and thus the mind observing several simple ideas to go constantly together, which being presumed to belong to one thing, or to be united in one subject, are called by one name, which we are apt afterwards to talk of, and consider, as one simple idea.

SUB'STANTIVE (*substantivus*: *Lat.*), in Grammar, a noun or name, denoting a thing without any regard to its qualities; as, on the other hand, an adjective is the name of a quality. Thus of the words 'red house,' the first denotes a quality, and is therefore an adjective; the second a thing, and is therefore a substantive.

SUB'STITUTE (*substitutus*, put instead of: *Lat.*), in Law, one delegated to act for another.——In the Militia, one engaged to serve in the room of another.

SUB'STITUTION (*substitutio*; from *substituo*, I put instead of: *Lat.*), in Chemistry, the replacing of one or more atoms of one element in a compound body by the same number of atoms of another element. Thus, when water is decomposed by zinc on adding sulphuric acid, an atom of the zinc is substituted for an atom of hydrogen, the latter being expelled.

SUBSTRA'TUM (*sub*, underneath; and *stratum*, a bed: *Lat.*), in Geology, a layer of earth laid under another.——In Metaphysics, the matter or substance supposed to furnish the basis in which the perceptible qualities inhere.

SUB'STYLE (*sub*, underneath; and *stylus*, a gnomon: *Lat.*), in Dialling, the line on which the gnomon stands.

SUBSUL'PHATE, in Chemistry, a sulphate with an excess of the base.

SUBSUL'PHURET, in Chemistry, a compound of sulphur, with a metal, &c., in a less proportion than is contained in a sulphuret.

SUBSUL'TUS (*subsulto*, I hop: *Lat.*), in Medicine, a twitching or convulsive motion; as *subsultus tendinum*.

SUBTAN'GENT, in Geometry, the part of the axis contained between the ordinate and tangent drawn to the same point in a curve.

SUBTEN'SE OF AN ARC (*subtendo*, I stretch underneath: *Lat.*), a right line opposite to an angle, supposed to be drawn between the two extremities of the arc; a *chord.*

SUBTRAC'TION (*subtraho*, I draw away from: *Lat.*), in Arithmetic, the taking of one number from another of the same kind or denomination, an operation by which the difference between two sums is found. ——In Law, the withdrawing or withholding of some right. Thus, the *subtraction* of a legacy is the withholding or detaining of it from the legatee by the executor; and in like manner, the withholding of any service, rent, duty, or custom, is a *subtraction*, for which the law gives a remedy.

SUBTRAHEND' (*subtrahendus*, to be subtracted: *Lat.*), in Arithmetic, the number to be subtracted or taken from another.

SUB'ULATE (*subula*, an awl: *Lat.*), in Natural History, shaped like an awl, that is narrow and tapering to a point.

SUB'URBS (*sub*, near to; and *urbs*, a city: *Lat.*), the buildings, streets, or parts that lie without the walls, but in the immediate vicinity of a city. Hence *suburban*, inhabiting or being situated near a city.

SUCCEDA'NEUM (*succedaneus*, that supplies the place of: *Lat.*), that which is used for something else; a *substitute.*

SUC'CINATE (*next*), in Chemistry, a salt formed by succinic acid and a base.

SUCCIN'IC ACID (*succinum*, amber: *Lat.*), in Chemistry, an acid obtained by the destructive distillation of amber. It has also been obtained by the action of nitric acid on stearic and margaric acids. It forms regular colourless crystals, and is a compound of carbon, hydrogen, and oxygen.

SUC'CINITE (same *deriv.*), a mineral of an amber colour, considered as a variety of garnet. It frequently occurs in globular or granular masses, about the size of a pea.

SUC'CINUM (amber; from *succus*, juice: *Lat.*), a genus of minerals. [See AMBER.]

SUC'CORY, chicory or wild endive. [See CHICORY.]

SUC'CULENT (*succulentus; from succus*, juice: *Lat.*), in Botany, an epithet for such plants as have thick and juicy leaves such as the cactus order and many plants growing near the sea.

SUC'CUS (*Lat.*), in Pharmacy, a term frequently employed to denote the extracted juice of different plants, as the *Succus glycorrhizæ*, Spanish liquorice, &c.

SUCCUS'SION (*succussio*, a shaking: *Lat.*), in Medicine, a rough mode of ascertaining the state of the chest in disease, by shaking the patient's body and then listening to the sound produced.

SUCK'ER (*sugo*, I suck: *Lat.*), the piston of a pump; also a piece of leather laid wet upon a stone, which, owing to the pressure of the atmosphere, adheres very closely, and is not to be pulled off without great force.——*Sucker* (*surculus: Lat.*), a young twig shooting from the stock or lower part of the stem, and afterwards rooting.

SUCK'ING-FISH. [See REMORA.]

SUCK'ING PUMP, or SUC'TION PUMP, the ordinary pump with two valves opening upwards. When the piston is drawn up, the valve it contains closes, and any water or air above it is raised by it; a vacuum being at the same time produced under it, the lower valve is forced open by the external air, which drives the air or water underneath to pass up through it. When the apparatus is once charged with fluid each upward stroke of the piston lifts the water which is above it, and, by atmospheric pressure, fills the vacant space which is under it with water that rushes from the well through the lower valve. The downward motion of the piston forces the water which is under it, and which cannot return to the well, on account of the closing of the lowervalve, to rushup through the now open valve in the piston. The valve in the piston is, therefore, open at the downward stroke, and closed at the upward; and the lower valve is open at the upward stroke, and closed at the downward. Suction, in the ordinary sense, is nothing more than the removal of atmospheric pressure from any interior space, so as to allow atmospheric pressure to act externally; thus when water is sucked up through a tube, the air is exhausted from the latter by the mouth, and then the pressure of the external air or the fluid forces it up through the tube.

SU'DOR AN'GLICUS (the English sweat: *Lat.*), in Medicine, an endemic fever, formerly known by the name of the *sweating sickness* of England. This disorder was thus named from its first appearing in this island; and acquired the title of *sudor*, from the patient suddenly breaking out into a profuse sweat, which formed its great characteristic feature. It was at first extremely fatal; it ultimately became less malignant, and finally disappeared. It carried off the patient in a few hours.

SUDORIF'ICS (*sudor*, sweat; and *facio*, I produce: *Lat.*), medicines which promote sweat or sensible perspiration.

SUE (*suivre*, to follow: *Fr.*), to institute legal process against a person; to prosecute in a civil action for the recovery of a real or supposed right; as to *sue* for debt or damages.

SUF'FERANCE (*sufferentia*, an enduring: *Lat.*), a term in Law applied to tenants; a tenant at *sufferance* being one that continues after his title ceases, without positive leave of the owner.

SUF'FRAGAN (*suffragor*, I support: *Lat.*), in ecclesiastical polity, a term of relation applied to a bishop, with respect to the archbishop who is his superior.

SUF'FRAGE (*suffragium: Lat.*), a vote given in deciding a controverted question, or in the choice of a man for an office or trust.

SUFFRU'TICOSE (*sub*, somewhat; and *fruticosus*, bushy: *Lat.*), in Botany, an epithet for plants which are woody at the base, but whose yearly branches decay; as sage, thyme, &c.

SUGAR, a compound of carbon, hydrogen, and oxygen, is produced by many animal and vegetable bodies. That which forms an article of commerce is the produce either of beet or of the sugar-cane; the latter, a plant which belongs to the order of grasses, cultivated in warm climates. It is the saccharum officinarum of botanists, which grows to the height of from five to seven feet. The stem of the mature plant is from one to two inches thick. It is coated with a layer of silicious matter, as in the bamboo, whilst the fibrous interior is saturated with the saccharine juice. The manufacture of sugar from the sugar-cane may be thus shortly sketched. The canes are taken, as soon as they are cut, to the mill, where they are subjected to great pressure between iron rollers. The juice thus expressed is boiled in open pans with lime, and the scum is carefully removed. It is then filtered and passed through animal charcoal in powder, previous to being concentrated. This process takes place either in open troughs heated by steam, or in vacuum pans where it is boiled in vessels from which the air has been exhausted. The concentration having proceeded to the proper extent, the sugar may be obtained separate from the liquid portion, or molasses, by the use of centrifugal machines, vessels with sides of wire-net through which the liquid is forced into an outer vessel when the machine is set in rapid revolution. On the concentrated hot juice having the consistency and granular appearance of thick oatmeal-porridge is placed in conical pots of earthenware. When it has cooled and solidified there appears a mass of sugar crystals with syrup amongst them. A plug is removed from the bottom of the vessel, and the syrup, in great part, drains away, leaving the sugar in the state known as Muscovado or raw moist sugar. There is still some syrup left behind, and some of this is removed by the process of claying, which consists in pouring a mixture of clay and water over the top of the pot to the depth of an inch or two. The water of the clay sinks gradually downwards through the porous mass of crystals, combining with the syrup, and carrying it off through the bottom of the pot. The sugar, after this treatment, is termed 'clayed.' It is the refiner's business to purify the sugars thus produced, and produce by delicate chemical and ingenious mechanical processes the white loaf sugar of which there is such a large consumption in this country. A large quantity of sugar is contained in the sap of the American maple (*Acer saccharinum*), and is obtained from it in many parts of North America; maple sugar being, in some places, the only kind which is used, particularly by those recently settled in the country. It is wholesome, and not disagreeable. The process of manufacturing it is very simple. The trees are bored obliquely from below upwards, at 18 or 20 inches above the ground, care being taken that the auger penetrates no more than half an inch into the alburnum, or white bark; as a greater discharge takes place at that depth than any other. The liquor is boiled, and the evaporation urged by an active fire, with careful skimming during the boiling; and the pot is continually replenished with more sap, till a large body has assumed a syrupy consistence. It is afterwards strained and boiled again over a very brisk fire, till it has acquired the requisite consistence for being poured into the troughs prepared to receive it. In 1859, 450,000 tons of sugar were consumed in the United Kingdom. It has been calculated that in England there is an annual average consumption of 32lbs. of sugar by each person, in France 10⅜lbs., in Ireland 6¼lbs., and in Italy only 2lbs.—Sugar is a *proximate* element of the vegetable kingdom, and is found in most ripe fruits, and many farinaceous roots. By fermentation sugar is converted into alcohol, and hence forms the basis of those substances which are used for making intoxicating liquors, as molasses, grapes, apples, malt, &c. Of all vegetable principles it is considered as the most wholesome and nutritious.

SUGAR-CANDY, sugar in the form of large crystals. If, when the sugar is boiled, ready for crushing, preparatory to being placed in the conical moulds [see SUGAR], instead of its being broken up with oars it is poured into pans, across which *threads* are strung, crystals will attach themselves to the threads; if these crystals are gradually dried, and then washed with lime-water to remove the molasses from their outer surface, the result is *sugar-candy*. During crystallization the sugar must be kept perfectly at rest, as on this depends the size and regularity of the crystals. It is used instead of loaf-sugar in India, China, &c.

SUIT (*suite*, a following: *Fr.*), in Law, an action or process for the recovery of a right or claim; an action at law, a proceeding by a rule in Chancery, a prosecution.

SUIT'OR (*last*), in Legal phraseology, one who attends a court to prosecute a demand of right in law, as a plaintiff, petitioner, or appellant.

SUL'CATE, or SUL'CATED (*sulcatus*, furrowed: *Lat.*), grooved or scored with deep broad channels.

SUL'PHATE OF COP'PER, in Chemistry, *Blue Vitriol*, a salt composed of sulphuric acid and oxide of copper. It is also a natural product, in the liquid form, of many copper mines, being the result of the infiltration of water over copper pyrites. It has a disagreeable metallic taste; and, when swallowed, it causes violent vomiting.

SUL'PHATE OF IRON. [See COPPERAS.]

SUL'PHATES, in Chemistry, salts formed by the union of sulphuric acid with different bases; as the sulphurate of soda, called *Glauber's salts*; the sulphate of magnesia, called *Epsom salts*; also the sulphate of copper, the sulphate of lime, the sulphate of zinc, &c.

SUL'PHIDE. [See SULPHURET.]

SUL'PHITES, in Chemistry, salts formed by the union of sulphurous acid with the different bases.

SUL'PHUR (*Lat.*), in Chemistry, *Brimstone*, a substance which is hard, brittle, and usually of a yellow colour, without any smell, unless rubbed or heated, and of a weak, though perceptible taste. It is a non-conductor of electricity; its specific gravity is 1·99. It melts at about 216°, becomes liquid at 250°, but viscid and of a deeper colour at 450°, and a little more fluid at 480°, its boiling point; it rises rapidly in vapour at 600°, and condenses in close vessels into *flowers of sulphur*, a fine powder consisting of minute crystals, the earthy substances and other impurities remaining behind. If precipitated from its alkaline solutions by hydrochloric acid it is in the form of a hydrate, sometimes termed *milk of sulphur*. It is obtained in commerce in the solid form, as *stick sulphur* or *cane brimstone*. Sulphur is dug out of the earth in various places where volcanic action is going on, particularly Italy and South America. It is one of the ingredients in the composition of gunpowder, and that which occasions it to take fire so readily. A prodigious quantity of sulphur is obtained from Solfatara, in Italy. This volcanic country everywhere exhibits marks of the agency of subterraneous fires; almost all the ground is bare, and white; and is everywhere sensibly warmer than the atmosphere in the greatest heat of summer. It is obtained in large quantities, thought not quite so pure, from *pyrites*, which is a combination of sulphur and iron.

SULPHU'RET, in Chemistry, a combination of sulphur with a metal: thus, *sulphuret of iron*, sulphuret of potassium. The sulphurets are now more usually termed *sulphides*.——*Sulphuret of iron*, a mineral composed of sulphur and iron, which is found in many parts of the world, and which is also called *pyrites* or fire-stone.

SULPHU'RIC ACID, in Chemistry, called also *oil of vitriol*, a very important acid, discovered about the end of the 15th century. It is obtained by burning a mixture of seven or eight parts of sulphur with one of nitrate of potash or soda. A current of air carries the products of combustion from the furnace into a large leaden chamber, the bottom of which is covered to a few inches in depth with water. The sulphurous and hyponitrous acid that pass into the chamber form with the vapour of water a crystalline solid, which, as soon as it falls into the water, is decomposed into sulphuric acid, that remains in solution, and nitric oxide, which ascends and unites with oxygen so as to again form hyponitrous acid; this, uniting with a new portion of sulphurous acid and the vapour of waters, again produces the crystalline solid, which falling into the water gives rise to a repetition of the same results. The oxygen of the atmosphere, therefore, indirectly changes the sulphurous into sulphuric acid, through the medium of nitric oxide. The weak acid, which, after some time, is found on the floor of the chamber, is concentrated first in leaden, and afterwards in platinum vessels. Sulphuric acid is a limpid, colourless fluid, having a spec. grav. of 1·8. It boils at 620°, and freezes at 15°. When diluted the temperature at which it freezes is different. It is highly caustic, and intensely acid. Its affinities are so strong that it expels all other acids, more or less perfectly, from their combinations. It absorbs water from the atmosphere, and when diluted with that fluid evolves great heat. It chars animal and vegetable substances with great rapidity. The strongest oil of vitriol of commerce contains one atom of the acid and one of water; the anhydrous acid consists of one atom of sulphur and three of oxygen. The presence of sulphuric acid, either free or in combination, is ascertained with great facility by a soluble salt of barytes, which, when it is present, even in minute quantities, throws down a white precipitate, the sulphate of barytes.

SUL'PHUROUS ACID, in Chemistry, the gas obtained by burning sulphur in atmospheric air or oxygen. Water absorbs 30 volumes of it. Its odour is suffocating; it bleaches straw, silk, wool, &c., and destroys the colour of violets, dahlias, &c. It extinguishes flame, and destroys animal life. The gas assumes the liquid form when subjected to a pressure of two atmospheres, or a temperature of 6°; and, when liquid, it evaporates with such rapidity as to freeze mercury.

SUL'TAN (*Arab.*), a title of royalty amongst Mohammedan nations. It signifies a despotic ruler. The Grand Sultan, or chief of the Turkish empire, is styled in his dominions the *Sultandin*, or protector of the faith, the *Padishah Islam*, or Emperor of Islamism, and the *Zil-Ullah*, or Shadow of God. The title of sultan was first assumed by Bayazid I., the chief of the Osmanlis, who reigned 1389-1403. The sultan as successor of the caliphs adds that title to his others, and since the Koran was supposed to be the treasure of divine and human laws, of which treasure the caliphs were depositaries, he is at once pontiff, legislator, and judge, the sacerdotal, regal, and judicial offices being united in his person. Although claiming to be absolute monarch he must govern in conformity with the principles of the Koran, and with the traditionary words called Sunna of the prophet; and he must also conform to the decision of the Ulema [which see], and to the Urfi or Kanun-name, the legislature established since the commencement of the empire.

SU'MACH (*Fr.*), the *Rhus coriaria* of botanists, nat. ord. *Anacardiaceæ*, a shrub of the south of Europe of considerable value, the powder of the leaves, peduncles, and young branches producing the *sumach* of commerce, much employed in tanning light-coloured leathers. In calico-printing, sumach affords, with a mordant of tin, a yellow colour; with acetate of iron, a gray or black; and with sulphate of zinc, a brownish-yellow. Both the leaves and seeds of the sumach are used in medicine as astringent and styptic.

SUM'MER (*sumer: Sax.*), one of the four seasons of the year; beginning, in the northern hemisphere, when the sun enters Cancer, about the 21st of June, and continuing for three months; during which time, the sun being north of the equator, renders this the hottest period of the year. In latitudes south of the equator just the opposite takes place, or, in other words, it is summer there when it is winter here. The summer quarter of meteorologists consists of June, July, and August.

SUM'MONS (*sub*, up; and *moneo*, I warn: *Lat.*), in Law, a warning or citation to appear in court; or a written notification signed by the proper officer, to be served on a person, warning him to appear in court at a day specified, to answer to the demand of the plaintiff.

SUMP, in Metallurgy, a round pit of stone, lined with clay, for receiving the metal on its first fusion.——In Mining, a pit sunk below the bottom of the mine.

SUMP'TUARY LAWS (*sumptuarius*, pertaining to expense: *Lat.*), those laws which in extreme cases, have occasionally been made to restrain or limit the expenses of citizens in apparel, food, furniture, &c. Sumptuary laws are abridgments of liberty, and of very difficult execution. Those of England were repealed by stat 1 Jac. I. c. 25.

SUN (*sonne: Ger.*), in Astronomy, the magnificent orb which, occupying the centre of our system, gives light and heat to all the planets. Its light constitutes the day, and the darkness which proceeds from its absence, or the shade of the earth, is the cause of night. This splendid luminary is 96,000,000 of miles distant from the earth; a canon ball travelling at a uniform velocity of 1600 feet in a second, would require ten years to reach it, from the earth Its diameter is 892,000 miles; its mass is 354,936 times that of the earth, and 800 times greater than the aggregate of the masses of all the planets and satellites; its density is about one-fourth that of the earth; a body which, at the earth's surface, would weigh one pound, would on that of the sun weigh 27 9lbs; and an ordinary man would be crushed to atoms by his own weight. The sun revolves on its axis in about 25 days; which is ascertained by means of the spots on his surface, and his equator is inclined to the ecliptic at an angle of about 7° 20′. The spots are subject to change, they banish, and reappear; one has been observed, covering an area of 1520 millions of square miles, that is, a space thirty times greater than the whole surface of the earth. There are several hypotheses regarding them, but none which is satisfactory. Some imagine that the luminous atmosphere of the sun is at a great distance from its mass; and that the calorific rays are so intercepted by clouds as to render it habitable, but there can be little doubt that a most intense heat prevails at its surface. It is also supposed that the heat and light constantly passing off may gradually diminish its bulk. It is highly probable that the sun has a proper motion in space, though some centuries of observation may be required to detect its laws. Astronomers have lately seen reason to think that the mean distance of the earth from the sun is not so great by four millions of miles as was formerly supposed. This distance is now put down at 91,328,000 miles. Various other numerical changes become necessary. Thus the circumference of the earth's orbit becomes 599,194,000 miles; and her mean hourly velocity 65,460 miles. The diameter of the sun is 850,100 miles. The numerical expressions for the distances, velocities, and dimensions of all the other planetary bodies will require corresponding correction. [See ASTRONOMY, PLANET, SOLAR SYSTEM, &c.]

SUN'DAY, the first day of the week, called also the *Lord's day*, in memory of the resurrection of Christ; and the *sabbath-day*, because substituted, in the Christian worship for the sabbath, or day of rest, in the old dispensation. This substitution was first decreed by Constantine the Great, A.D. 321, before whose time both the old and new sabbath were observed by Christians. [See SABBATH.]

SUN'-FLOWER, a plant of the genus *Helianthus*, so called from its turning to the sun. [See HELIANTHUS.]

SUN'-HEMP, a coarse fibre employed in India in the manufacture of rough bags. It is furnished by the *Crotolaria juncea*, a leguminous plant which grows from four to six feet high, and bears masses of laburnum-like flowers.

SU'PER (*Lat*), a prefix used in chemical technology, with many words, denoting an excess; as *super*sulphate of potash, in which there is an excess of sulphuric acid.

SUPERCAR'GO, a person in a merchant's ship appointed to manage the sales and superintend all the commercial concerns of the voyage.

SUPEREROGA'TION (*super*, besides; and *errogatio*, a giving out: *Lat.*), in Roman Catholic theology, a term applied to such works as a man does which exceed the measure of his duty. This doctrine is condemned by the Church of England, in her 14th article

SUPERFI'CIES (*Lat*), the *surface*, or exterior face of a thing; as the *superficies* of a plane, or of a sphere.

SUPER'LATIVE (*superlativus: Lat.*), in Grammar, the name usually given to the third or highest degree of comparison: formed in the Teutonic languages, by the addition of 'est'

SUPERNU'MERARY, in Military affairs, is an epithet for the officers and non-commissioned officers attached to a regiment for the purpose of supplying the places of such as fall in action, &c.

SUPERPOSI'TION (*superpono*, I place over: *Lat.*), in Geology, a lying or being situated upon or above something.

SUPERSCAPULA'RIS (*super*, above; and *scapula*, the shoulder blade: *Lat.*), in Anatomy, a muscle seated upon the scapula or shoulder-blade.

SUPERSE'DEAS (*Lat.*), in Law, a writ or command to suspend the powers of an officer in certain cases, to stay proceedings, and in certain cases to discharge prisoners.

SUPERSTRUC'TURE (*superstruo*, I build upon: *Lat.*), any kind of building raised on a foundation or basis; the word being used to distinguish what is erected on a wall or foundation, from the foundation itself.

SUPERTON'IC, in Music, the note next above the key-note.

SUPINA'TORS (*supino*, I put anything on its back: *Lat.*), in Anatomy, two muscles of the arm; the one called the *supinator longus*, the other the *supinator brevis*, both serving to turn the palm of the hand upwards.

SUP'PLEMENT (*supplementum*, a filling up: *Lat.*), in Literature, an addition made to a book or paper, by which it is rendered more full and complete.——*Supplement of an arc*, in Geometry, the number of degrees which it wants of being an entire semi-circle; as a *complement* signifies what an arc wants of being a quadrant.

SUPPORTERS (*supporto*, I carry: *Lat.*), in Heraldry, figures placed by the side of the shield, and appearing to support it. Thus the lion and unicorn are the supporters of the British sovereign's arms. In modern English Heraldry, the use of supporters is limited to Sovereigns and Princes of the blood royal, Peers of the Realm, Knights of the Bath, Knights Bannerets, Baronets of Nova Scotia, and such as receive a special license from the king. In case of marriage of two parties, both of whom are entitled to supporters, one of each may be borne.——*Supporters*, in Architecture, images which serve to bear up any part of a building in the place of a column.

SUPPURA'TION (*suppuratio*: *Lat.*), in Medicine, the process of generating purulent matter, or of forming pus, as in a wound or abscess. Also, the matter generated by suppuration.

SUPRALAPSA'RIAN, in Theology, one who maintains that God, antecedent to the fall of man, decreed the apostacy and all its consequences, determining to save some and condemn others, and that in all he does he considers his own glory only.

SUPREM'ACY (*supremitas*, the highest honour: *Lat.*), in English polity, the supreme and undivided authority of the sovereign over all persons and things in this realm, whether spiritual or temporal.——*Oath of supremacy*, in Great Britain, an oath which acknowledges the supremacy of the sovereign in spiritual affairs, and abjures the pretended supremacy of the pope.

SURBASE (*Fr.*), in Architecture, the upper base of a room, consisting of the cornice of the dado.

SURCIN'GLE (*supra*, above; and *cingulum*, a girdle: *Lat.*), the girdle with which clergymen bind their cassocks. Also a girth for horses.

SUR'CULUS. [See SUCKER.]

SURD (*surdus*, indistinct: *Lat.*), in Arithmetic and Algebra, a magnitude not expressible by rational numbers, thus the square root of 2. Surds cannot be expressed exactly by ordinary notations, and are represented by prefixing the radical sign as $\sqrt{8}$, the square root of 8: $\sqrt[3]{7}$, the cube root of 7, &c.; they are termed also, *irrational* or *incommensurable* quantities.

SU'RETY (*sureté*: *Fr.*), in Law, one who enters into a bond or recognizance to answer for another's appearance in court, for his payment of a debt, or for the performance of some act, and who, in case of the principal's failure, is compellable to pay the penalty, debt, or damages.

SURF, the swell of the sea which bursts upon the shore, or against any rock that lies near the surface of the sea. A *surge* is a great wave rolling above the general surface of the water.

SUR'GERY (corrupted from chirurgery: *cheir*, the hand; and *ergon*, a work: *Gr.*), that branch of medical science which is concerned with the cure of disease, or the prevention of the ill effects arising from injury to the human body by means of operations performed by hand assisted by suitable instruments.

SURMUL'LET, or Red Mullet, a marine fish. [See MULLET.]

SUR'NAME (*surnom*: *Fr.*), the family name; the name or appellation added to the baptismal or Christian name. Camden derives it from *sur*, as being added over or above the other, in a metaphorical sense only. The most ancient *surnames* were formed by adding the name of the father to that of the son, in which manner were produced several English *surnames*, ending with the word son; thus, *Thomas William's son*, makes *Thomas Williamson*. The feudal system introduced a second description of *surnames*, derived from the names of places: as Sutton, Acton, &c.; and these were originally written with the particle *de* or *of*; as Henry de Sutton. Many surnames have been adopted from occupations, *Miller*, *Cooper*, *Taylor*, &c.; and many from personal peculiarities, *Long*, *Tall*, *Short*, &c.

SURREBUT'TER, in Law, the answer of the plaintiff to the defendant's rebutter.

SURREJOIN'DER, in Law, a second defence, as the *replication* is the first, of the plaintiff's declaration in a cause: it is an answer to the rejoinder of the defendant.

SURREN'DER (*surrendre*, to yield: *old Fr.*), in Law, a deed testifying that the tenant for life or years of lands, &c. yields up his estate to him that has the immediate estate in remainder or reversion.

SUR'ROGATE (*surrogatus*, substituted: *Lat.*), in the Civil Law, a deputy, or person substituted for another. The word is most commonly used as the title of a bishop's chancellor.

SUR'TURBRAND, fossil wood, found in great abundance in Iceland. It extends through the whole of the north-western part of the island, and is evidently a subterranean forest, impregnated with bituminous matter, and compressed by the weight of superincumbent matter.

SURVEY'ING (*survoir*, to overlook: *old Fr.*), the art of measuring land, laying down its dimensions upon paper, and finding its content or area. It is of two kinds, *land surveying* and *marine surveying;* the former having generally in view the measure or contents of certain tracts of land, and the latter the position of beacons, towers, shoals, coasts, &c. Those extensive operations which have for their object the determination of the latitude and longitude of places, and the length of terrestrial arcs in different latitudes, also fall under the general term *surveying*, though they are frequently called *trigonometrical surveys*. The operations of the surveyor are carried on by means of various instruments, such as the theodolite, the chain, &c., and he requires an acquaintance with practical geometry, trigonometry, the methods of calculation, &c.

SUS (*Lat.*), in Zoology, a generic term for the animal which is well known by the name of the *hog*, which see.

SUSPEN'SION (*suspendo*, I interrupt

Lat.), temporary privation of power, authority, or rights, usually intended as a punishment. A military or naval officer's suspension takes place when he is put under arrest.——In Law, prevention or interruption of operation; as the *suspension* of the habeas corpus act.——SUSPENSION, in Rhetoric, a keeping of the hearer in doubt and in attentive expectation of what is to follow, or what is to be the inference or conclusion from the arguments or observations.——SUSPENSION BRIDGES. [See BRIDGE.]——SUSPENSION OF ARMS, a short truce agreed on by hostile armies, in order to bury the dead, make proposals for surrender, &c.——POINTS OF SUSPENSION, in Mechanics, those points in the axis or beam of a balance to which the weights are applied, or from which they are suspended.

SUTTEE' (*satee*, pure: *Sans.*), the act of sacrifice by which a Hindoo widow immolates herself on the funeral pile of her husband. Though none of the sacred books of the Hindoos absolutely command the *suttee*, they speak of it as highly meritorious, and the means of obtaining eternal beatitude. It is believed also to render the husband and his ancestors happy, and to purify him from all offences, even if he had killed a Brahmin. Since the year 1756, when the British power in India became firmly established, upwards of 70,000 Hindoo widows have thus been sacrificed. On one occasion twenty-eight widows of a rajah were burned with his body. The institution has been suppressed by the English.

SU'TURE (*sutura*, a seam: *Lat.*), in Anatomy, the union of bones by means of dentiform margins; as is the case with the bones of the skull.

SWAIN'MOTE, or SWEIN'MOTE, in Law, one of the old forest courts formerly held before the verderers, as judges, by the steward of the swainmote; the swains (*swein*, a countryman: *Sax.*) composing the jury.

SWAL'LOW. [See HIRUNDO, and SWIFT.]

SWAMP (*Sax.*), wet and spongy land in low situations, but not usually covered with water. It differs from a *bog* and a *marsh*, in producing trees and shrubs, while the latter produce only herbage, plants, and mosses.

SWAMP-ORE, in Mineralogy, an ore of iron found in swamps and morasses, the colour of which is a dark yellowish brown or gray. It is called also *bog-ore*, or indurated bog iron ore.

SWAN, the name given to some large aquatic birds belonging to the genus *Cygnus*. Four species of this genus are placed amongst British birds. The plumage is of a pure white colour, and its long arching neck gives it a noble appearance. In northern climates, the swans are the ornament of the rivers and lakes, over which they seem to preside, from the majesty, ease, and grace of their movements. They swim rapidly, and their flight is powerful and long continued; they live in society, attain a great age, and make their nests near the margin of the water, upon the ground. The wild or whistling swan (*C. ferus*) has a black bill. The tame or mute swan (*C. olor*) has an orange-coloured bill and has a projecting black callous tubercle or knob on the base of the upper mandible. The black swan (*Cygnus atratus*) has a plumage which is almost all of a deep black; and at the base of its upper mandible, near the nostrils, is a bifid protuberance, which is wanting in the female.

SWEDENBOR'GIANS, the followers of Swedenborg, a Swedish nobleman who died in 1772. His doctrines were founded on a presumed analogy between spiritual and natural things, and are full of mysticism. He considered Christ as the one God in whom is centred the Divine Trinity; he insisted on the necessity for keeping the divine commandments, in which is included the performance of every duty. The Swedenborgians have places of worship in London, &c., and are greatly increasing in America.

SWIETENIA, in Botany, a genus of plants. The principal species is the *Swietenia mahogoni*, the mahogany-tree, or native of Central America. [See MAHOGANY.]

SWIFT, the name given to birds of the genus CYPSELUS. They are closely allied to the swallows and martins, but these have one of the toes directed backwards, whereas the toes of the swift are all directed forwards. The common swift (*C. murarius*) builds under the eaves of houses, or in holes in steeples. It is in the habit of continuing on the wing in the rapid pursuit of insects for hours together.

SWIM'MING, the progressive motion of an animal body in water. A large proportion of the animal tribes are furnished with a greater or less capacity for swimming. Fishes are wholly adapted to it; amphibious creatures, as much, if not more, than to walking; web-footed birds pass a considerable part of their existence upon the surface of the water, and many of them occasionally make their way beneath it. The same may be said of innumerable species of insects; and all quadrupeds are at least capable of preserving their lives, if accident immerses them in this element, while some resort to it with peculiar readiness. Man alone is incapable of swimming, without learning to do so as an art. The reason of this peculiar inability of the human race is attributed to the construction of the body, and especially of the head, from which results a situation of the centre of gravity wholly different from that in quadrupeds. Of man, the head with respect to the body, and compared with the heads of other animals, as proportioned to their bodies, is singularly heavy; a quality occasioned by the larger quantity of flesh, bones, and brain with which it is furnished; and the absence of those sinuses or cavities which, like air-bladders, lighten that of other animals. The head of a man, therefore, sinks by its own gravity; and, thus exposing the body to fill with water, causes him to drown. Brutes, on the other hand, are able to keep their nostrils above water with facility, and, thus respiring freely, are, on the principles of statics, out of danger. From these observations it will follow, that the *art of swimming*, which can be acquired by exercise only, chiefly consists in keeping the head above water; and that the hands and feet are to be used as oars and helm, in guiding the course of the vessel. With proper management the human body is capable of floating, as its specific gravity is, in reality less than that of water. [See DROWNING.]

SWING. A ship at anchor is said to *swing* when she changes her position at the turn of the tide.

SWING'WHEEL, in Horology, the wheel which drives the pendulum. In a watch, or balance-clock, it is called the *crown-wheel*.

SWIV'EL, in Gunnery, a piece of artillery, fixed on a socket on the top of a ship's side, stem, or bow, or in her tops, in such a manner as to be turned in any direction. ——A strong link of iron used in mooring ships, and which permits the bridles to be turned round.

SWORD-FISH, the name given to some fishes belonging to the genera *Xiphias* and *Histiophorus*. Their snouts are armed with a long bony weapon, with which they attack other fishes. The common sword-fish (*Xiphias gladius*) inhabits the Atlantic and the Mediterranean, and attains the length of 14 or 15 feet. It has been known to drive its sword into a ship, and there leave it firmly embedded.

SYB'ARITE an inhabitant of Sybaris, formerly a town on the Gulph of Tarentin in Italy, whose inhabitants, having become enervated by slavery to sensual pleasures, were easily subdued by the Crotonians. The term is applied metaphorically to designate an effeminate voluptuary.

SYCEE SILVER (*se sze*, fine gloss silk: *Chin.*), a silver currency among the Chinese. It is formed into ingots, stamped with the mark of the office from which they are issued. They are of various weights, but generally amount to ten *taels* each.

SYC'ITE (*sukites*, like a fig: *Gr.*), or FIG-STONE, a name sometimes given to nodules of flint or pebbles which resemble a fig.

SYC'OMORE (*sukomoros*, the fig-mulberry, *Gr.*). The true sycomore is an eastern tree belonging to the fig tribe, the *Ficus sycomoros* of botanists. The name *sycamore* has been given to a species of maple grown in Britain, the *Acer pseudo-platanus* of botanists.

SYC'OPHANT (*sukophantēs*; from *sukon*, a fig; and *phaino*, I inform against: *Gr.*), an obsequious flatterer or parasite. This word was originally used to denote an informer against those who plundered sacred fig-trees, or exported figs contrary to law. Hence, in time it came to signify a tale-bearer or informer in general; thence a flatterer, deceiver, or parasite.

SYENITE in Geology, a plutonic rock resembling granite in external appearance, but composed of quartz, felspar, and hornblende. It derives its name from having been obtained at the ancient quarries of Syene in Egypt. When it loses its quartz it gradually passes into syenitic greenstone, a rock of the trap series.

SYL'LABLE (*sullabē*; from *sullambano*, I take together: *Gr.*), in Grammar, a combination of letters uttered by a single effort or impulse of the voice, as *can*; or a single letter, as *o* in *over*. At least one vowel or open sound is essential to the formation of a syllable.

SYL'LABUS (a list: *Lat.*; from *sullabos*: *Gr.*), an abstract, or compendium containing the heads of a discourse, &c.

SYLLEP'SIS (*sullēpsis*; from *sullambano*, I take together: *Gr.*), in Grammar, a figure by which we conceive the sense of words otherwise than the words import, and construe them according to the intention of the author. Also, where two nominative cases singular of different persons are joined to a verb: or substantives of different gender to the same adjective—as *Rex et Regina beati*, or the agreement of a verb or adjective, not with the word next to it, but with the most worthy: as 'Rex et Regina beati.'

SYL'LOGISM (*sullogismos*; from *sullogizomai*, I bring at once before the mind: *Gr.*), in Logic, an argument consisting of three propositions; the two first of which are called the *premises*, and the last the *conclusion*. Syllogisms are nothing more than our reasoning reduced to form and method: and every act of reasoning implies three several judgments, so every syllogism must include three distinct propositions. Thus, in the following syllogism:—'Every creature possessed of reason and liberty is accountable for his actions;' 'Man is a creature possessed of reason and liberty:' 'Therefore man is accountable for his actions.' These propositions are denominated the major, the minor, and the conclusion. ——An *analogical syllogism* founds the conclusion upon similitude; 'As the base is to the column, so is justice to the commonwealth; but if the base be withdrawn, the column is overturned; therefore if justice is taken away, the commonwealth is overturned.'——An *hypothetical syllogism* is one in which the conclusion is deduced from an hypothetical premiss, called the major, and a categorical premiss called the minor. A syllogism is either *conditional* or *disjunctive*; if conditional it is either *constructive* or *destructive*. A disjunctive may easily be reduced to a conditional syllogism. 'With a *categorical syllogism*, that is, one containing three categorical propositions—and all syllogisms can be reduced to such—if two of the terms agree with the same third term, they agree with one another; if one of the terms agrees with and another disagrees with, the same third term, the two first disagree with one another.' Every syllogism has three terms, the middle term, and two extremes—designated the major and minor terms. The subject of the conclusion is the *minor* term; its predicate, the *major term*; and that with which they are compared is the middle term. In the major premiss, the major term is compared with the middle; in the minor premiss the minor term is compared with the middle; and in the conclusions, the major and minor terms are compared together. The middle term must be distributed once at least in the premises—that is, it must be the subject of a universal, or the predicate of a negative proposition; otherwise the two extremes may be compared, not with the *same* thing, but with two *different* parts of the middle term. No term must be distributed in the conclusions which is not distributed in one of the premises; otherwise, the *whole* term would be employed in the conclusion, and a *part* of it only in the premiss, in which case the error is termed an *illicit process* of the major or minor premiss. Nothing can be inferred from *two negative* propositions. If one premiss is negative, the conclusion must be negative, because one of the extremes disagreeing with the middle term, they must disagree with one another.——The *mood* or *mode* of a syllogism is the designation of its propositions, according to the respective *quantities*, that is, whether universal or particular; and *qualities*, that is, whether affirmative or negative: A is used to represent a universal affirmative proposition, thus—'all men are mortal:' E, a universal negative, thus—'no man is always wise:' I, a particular affirmative, thus—'some men are revengeful:' and O, a particular negative, thus—'some men do not live to be old.' There may be sixty-four combinations of these letters, and therefore of the propositions which they represent; but many of the corresponding syllogisms err against some of the rules given above; and only eleven will be found to afford correct syllogisms.——The *figure* of a syllogism consists in the situation of the middle term, with reference to the major and minor terms. In the 1st figure, the middle term is the subject of the major premiss, and the predicate of the minor; in the 2nd figure, the middle term is the predicate of both premises; in the 3rd figure, it is the subject of both; and in the 4th figure, it is the predicate of the major, and the subject of the minor. Multiplying the moods by the figures, we obtain forty-four different syllogisms; but of these five in each figure would err against some of the rules given above; and of the remaining twenty-four, five are unnecessary, particular conclusions being inferred in them, from premises which would warrant universal. The remaining nineteen have been expressed by the following *mnemonic* lines.

Fig. 1.—4 Moods. *b*A*rb*A*r*A, *c*E*l*A*r*E*nt*, *d*A*r*II, *f*E*r*IO*que*, prioris.
Fig. 2.—4 Moods. *c*E*s*A*r*E, *c*A*m*E*str*E*s*, *f*E*st*I*n*O, *b*A*r*O*k*O, secundæ.
Fig. 3.—6 Moods. *tertia*, *d*A*r*A*pt*I, *d*I*s*A*m*I*s*, *d*A*t*I*s*I, *f*E*l*A*pt*O*n*, *b*O*k*A*rd*O, *f*E*r*I*s*O*n*, habet: quarta insuper addit.
Fig. 4.—5 Moods. *br*A*m*A*nt*I*p*, *c*A*m*E*n*E*s*, *d*I*m*A*r*I*s*, *f*E*s*A*p*O, *f*E*r*I*s*O*n*.

As examples we may select a syllogism in the first mood of the first figure. 'A. all men are animals: A. all animals are mortal: *ergo* (therefore: *Lat.*), A. all men are mortal.' And the last mood of the fourth figure, 'E. No good man is cruel: I. some cruel men are brave: therefore, O. some brave men are not good men.' Almost every argument, however disguised by the language, may be reduced to a mood in one of the first three figures. In *reducing* a syllogism, the premises may be *illatively converted*, or transposed [see ILLATIVE CONVERSION]. The major does not always precede the minor premises. 'John is a just man: just men pay their debts: therefore John pays his debts,' is a syllogism in *Barbara*, with the major premises following the minor.

SYM'BOL (*sumbolon*; from *sumballo*, I bring together: *Gr.*), a word of many meanings, though used at present with but one. The original signification was the making several things contribute to form one whole; thus creeds were termed *symbols*, being a collection of articles of faith. But the word is now used to express outward appearances, intended to indicate something: in which sense the Greeks called their standards symbols, and the early Christians, all rites, ceremonies, sacraments, &c.——*Symbol*, in Chemistry, an abbreviation of the name of all elementary body; thus *Ag* is written for silver (Argentum); *Pb* for lead (Plumbum).——In the Eucharist, the bread and wine are called by Protestants *symbols* of the body and blood of Christ.——*Symbolical books*, are such as contain the creeds and confessions of different churches.——*Symbolical philosophy*, is a philosophy expressed by hieroglyphics.

SYMPATHET'IC INK, the name given to any chemical composition which may be used as ink, but the writing will be invisible until the paper is warmed, or until it is washed over with some other liquid. Thus if the ink be a solution of sulphate of iron, the writing will not be perceived until it is washed with tincture of galls. Again, if we write with a solution of hydrochlorate of copper, nothing will be seen upon the paper until it is held to the fire. The writing will become invisible once more when the paper is cool.

SYM'PATHY (*sumpatheia*; from *sumpatheo*, I feel along with: *Gr.*), the feeling of being affected similarly to some other person. According to Adam Smith it is in sympathy that our moral sense takes its rise.——In Medicine, *sympathy*, or 'consent of parts,' signifies a correspondence of various parts of the body in similar sensations or affections; or an affection of the whole body or some part of it, in consequence of an injury or disease of another part.——A *sympathetic disease* is one which is produced by a remote cause, as when a fever follows a local injury. In this case, the word is opposed to *idiopathetic*; which denotes either an original disease, or that which is produced by a proximate cause.——In Anatomy, the term *sympathetic* is applied to two nerves (the great intercostal and the facial nerves) from the opinion that their communications are caused by sympathies.

SYM'PHONY (*sumphōnia*: *Gr.*), in Music, primarily signifies a consonance or harmony of sounds, agreeable to the ear, either vocal or instrumental, or both. It means, at present, a piece of concerted music composed of several parts. Mozart and Beethoven have written some fine compositions of this class.

SYM'PHYSIS (*sumphusis*, a growing together: *Gr.*), in Anatomy, an immovable union of bones.——In Surgery, a coalescence of a natural passage; also, the first intention of cure in a wound.

SYMPO'SIARCH (*sumposiarchos*; from *sumposion*, a drinking party; and *archo*, I govern: *Gr.*), among the ancients the director and manager of an entertainment. This office was sometimes performed by the person at whose expense the feast was provided; and sometimes by the person whom he thought fit to nominate. The feasts of the ancient Greeks were termed symposia; but those of the Romans *convivia* (*con*, along with; and *vivo*, I live: *Lat.*); and Cicero remarks that the Romans were much more happy than the Greeks in choosing a word to signify an entertainment; since their idea was founded on *mutual intercourse*; while that of the Greeks had reference to the mere animal gratification derived from *drinking*.

SYMP'TOM (*sumptōma*; from *sumpipto*, I fall in with: *Gr.*), in Medicine, any appearance in a disease which serves to indicate or point out its cause, approach, duration, event, &c. Particular symptoms which more uniformly accompany a morbid state of the body, and are characteristic of it, are called *pathogonomic* or *diagnostic* symptoms. In a strict sense, however, *symptom* means no more than the consequences of diseases, and of their causes, exclusive of the diseases and causes themselves.——A *symptomatic* disease is one which proceeds from some prior disorder; as a symptomatic fever, proceeding from local pain or local inflammation. It is opposed to *idiopathic*.

SYMPTOMATOL'OGY (*sumptōma*, a symptom; and *logos*, a discourse: *Gr.*), that part of the science of medicine which treats of the symptoms of diseases.

SYNÆ'RESIS (*sunairesis*; from *sunaireo*, I bring together: *Gr.*), in Grammar, the contraction of two syllables into one: by the formation of a diphthong, or by rendering one of them mute; as Atreides, for Atreides. It is also termed *crasis*.

SYN'AGOGUE (*sunagōgē*, literally, a bringing together: *Gr.*), the building appropriated to the religious worship of the Jews; or the congregation who assemble in it, for the performance of their religious rites. It is supposed that there was no synagogue until after the captivity of Babylon. The service of the synagogue consisted anciently, as at present, of prayers, reading, and exposition of the Scriptures, and preaching. The lessons from Scripture consisted of passages from Deuteronomy and Numbers, the law, and the prophets.

SYNALŒ'PHA (*sunaloiphē*, literally a melting together: *Gr.*), in Classical prosody, the running of the syllable of one line into the first syllable of the next. It is occasionally used in modern languages, even including our own.

SYNARTHRO'SIS (*sunarthrōsis*; from *sunarthroo*, I link together: *Gr.*), in Anatomy, a species of articulation, where there is only an obscure motion, as in the bones of the carpus and metacarpus, &c.; or where there is no motion at all, as in the sutures of the skull.

SYN'CHISIS (*sun*, together; and *chusis*, a pouring out: *Gr.*), in Rhetoric, a confused and disorderly placing of words in a sentence.

SYNCHONDRO'SIS (*sun*, with; and *chondros*, a cartilage: *Gr.*), in Anatomy, a species of *symphysis*; being the union of two bones by means of a cartilage: as in the vertebræ.

SYNCHORE'SIS (*sun*, along with; and *chōrēsis*, a holding: *Gr.*), in Rhetoric, a figure of speech in which an argument is scoffingly conceded, for the purpose of retorting it more pointedly.

SYN'CHRONISM (*sun*, along with; and *chronismos*, a duration: *Gr.*), in Chronology, concurrence of two or more events in time. ——*Synchronal*, simultaneous, or happening at the same time.

SYNCLI'NAL, in Geology. [See ANTICLINAL.]

SYN'COPATE (*next*), in a primary sense, to contract; as a word, by taking one or more letters or syllables from the middle. ——In Music, to prolong a note begun on the unaccented part of a bar, to the accented part of the next bar; or to connect the last note of a bar with the first of the following.

SYN'COPE (*sunkopē*, a cutting short: *Gr.*), in Grammar, an elision or retrenchment of a letter or syllable from the middle of a word.——In Medicine, a swooning, in which the patient continues without any sensible motion or respiration; accompanied with a suspension of the action of the brain and a temporary loss of sensation and volition.——In Music, the prolonging of a note, begun on the unaccented part of a bar, to the accented part of the next bar; or the division of a note introduced when two or more notes of one part answer to a single note of another. The word *syncopation* is, however, more frequently used in music.

SYN'CRISIS (*sun*, together; and *krisis*, a judgment: *Gr.*), in Rhetoric, a figure of speech in which opposite persons or things are compared.

SYNDES'MUS (*sundesmos*, literally that which binds together: *Gr.*), in Anatomy, a ligament for binding together the bones and other parts.——In Grammar, a *conjunction*.

SYN'DIC (*sundikos*, helping in a court of justice: *Gr.*), an officer invested with different powers in different countries; generally a kind of magistrate entrusted with the affairs of a city or community. The university of Cambridge has its *syndics*: and in Paris almost all the companies, the university, &c. have theirs. In France, the creditors of a bankrupt appoint syndics or directors from among themselves.

SYNEC'DOCHE (*sunekdochē*: *Gr.*), in Rhetoric, a figure or trope by which the whole of a thing is put for a part, or a part for the whole; as the genus for the species, or the species for the genus, &c.

SYNE'CHIA (*sunecheia*, an unbroken

connection: *Gr.*), in Medicine, a concretion of the iris of the eye with the cornea, or with the capsule of the crystalline lens.

SYNGENE'SIA (*sun*, along with; and *genesis*, a production: *Gr.*), the 19th class of the Linnæan system of plants, containing several orders, in which the stamens are united in a cylindrical form by the anthers. Such plants constitute the nat. ord. *Compositæ*.

SY'NOCHA (*sunochē*, a meeting: *Gr.*), in Medicine, a species of continued fever, attended with symptoms denoting general inflammation in the system.

SY'NOCHUS (same *deriv.*), in Medicine, a species of mixed fever, commencing with symptoms of synocha, and terminating in typhus.

SYN'OD (*sunodos*; from *sun*, together; and *odos*, a way—literally, a journeying together: *Gr.*), in Ecclesiastical affairs, a council or meeting to consult on matters of religion. In Scotland, a synod is composed of several adjoining presbyteries. The members are the ministers, and a ruling elder from each parish.——*Synod*, in Astronomy, a conjunction, or concourse of two or more stars or planets, in the same optical place of the heavens.——*Synodical month*, a lunar month; the period from one conjunction of the moon with the sun to another. This is called also a *lunation*, because in the course of it the moon exhibits all its phases.

SYN'ONYME, or **SYN'ONYM** (*sunōnimia*, a likeness of name: *Gr.*), a word having the same signification as some other word. We rarely find two words precisely *synonymous* in all situations; though many are sometimes synonymous, and at other times not so. Thus, when we speak of the large rolling swell of the sea, we may call it a *wave*, or a *billow*; but when we speak of the small swell of a pond, we may call it a *wave*, but not a *billow*.

SYNOP'SIS (a seeing all together: *Gr.*), a collection of things or parts so arranged as to exhibit the whole or the principal parts in a general view.

SYNO'VIA (*sun*, along with; and *oon*, an egg: *Gr.*), in Anatomy, the fluid which lubricates the articulations of the bones; and which is for that purpose secreted in the cavities of the joints. It is glairy, and somewhat resembles the white of an egg.

SYN'TAX (*suntaxis*, literally, a putting together in order: *Gr.*), that division of grammar which analyzes the dependence of parts of speech upon one another, and supplies rules for their mutual government. Syntax, as an art, may be divided into two branches: the one common to all languages, and by which words are made to agree in gender, number, case, person, and mood; the other peculiar to each language, and by which one mood is made to govern another, and the consequent variations effected: the first of these is called *concord*; the second *government*. It has been said that the first merit of language is intelligibility; its first grace, purity; and that every other excellence is subordinate. Syntax, then, especially deserves attention: as neither intelligibility nor purity of style can be found where the rules of syntax are violated.

SYN'THESIS (*sunthesis*, a putting together: *Gr.*), in Antiquity, a loose robe worn by the Romans at their meals.——In Chemistry, the uniting of elements into a compound: the opposite of *analysis*, which is the separation of a compound into its constituent parts.——In Logic, that process of reasoning in which we advance by a regular chain from principles before established or assumed, and propositions already proved, till we arrive at the conclusion. The *synthetical* is therefore opposed to the *analytical* method.

SY'PHERING, in Ship-building, the lapping the edge of one plank over the edge of another in constructing the bulkheads.

SYRIN'GA (*surinx*, a pipe: *Gr.*; from its branches constituting tubes, when the pith is removed), in Botany, a genus of plants, nat. ord. *Oleaceæ*, containing the lilacs. The species cultivated in this country are natives of Persia. The shrub to which the name syringa is popularly given is a species of *Philadelphus*, a native of the south of Europe.

SYRINGOT'OMY (*surinx*, a pipe; and *tomē*, a cutting: *Gr.*), in Surgery, the operation of cutting for the fistula.

SYSSARCO'SIS (*sussarkōsis*; from *sun*, with; and *sarx*, flesh: *Gr.*), in Anatomy, a species of union of bones in which one is united to another, by means of an intervening muscle.

SYS'TEM (*sustēma*, a complex whole: *Gr.*), in Science and Philosophy, a whole plan or scheme, consisting of many parts connected in such a manner as to create a chain of mutual dependencies; or a regular union of principles or parts forming one entire thing. Thus, we say, the planetary *system*, or the whole of the bodies supposed to belong to each other; a *system* of Botany, or that which comprehends the whole science of plants; a *system* of Philosophy, or a theory or doctrine which embraces the whole of philosophy.

SYS'TOLE (*sustolē*, a contracting: *Gr.*), in Anatomy, the contraction of the ventricles of the heart, for expelling the blood and carrying on the circulation; the opposite state to which is called the *Diastole*, or dilatation of the heart.——In Grammar, the shortening of a long syllable.

SYS'TYLE (*sun*, together; and *stulos*, a column: *Gr.*), in Architecture, the disposition of columns in a building near to each other, but not quite so much so, as in the *pycnostyle*; the intercolumniation being only two diameters of the column.

SYZY'GIA (*suzugia*, a yoking together: *Gr.*), in Grammar, the coupling different feet together, in Greek or Latin verse.

SYZ'YGY (same *deriv.*), in Astronomy, a term equally used for the conjunction and opposition of the moon and planets, with the sun.

T

T, the twentieth letter and sixteenth consonant in the English alphabet, is a *dental*, or *palato-dental*; and susceptible of numerous interchanges, both in ancient and modern languages. It is numbered among the mutes, and differs from *d* chiefly in its closeness, the strength with which the breath is emitted in pronouncing *t* being all that distinguishes them. Its natural sound is heard in *take, turn, bat, bolt, butter*. Its use is to modify the manner of uttering the vocal sound which precedes or follows it. When *t* is followed by *h*, as in *think* and *that*, the combination forms a distinct sound, which is almost peculiar to the English language, and for which we have no single character; these sounds differ, *think* being aspirated, and *that* being vocal. Another sound is also produced by its combination with *i*, the letters *ti* usually passing into the sound of *sh*, as in *nation, position, substantiate*, &c. In a few words, the combination *ti* has the sound of the English *ch*, as in *Christian*. As an abbreviation, T was used by the Romans for Titus, Tullius, &c.: as M. T. Cicero, Marcus *Tullius* Cicero. The Roman Tribunes indicated their assent to the decrees of the senate, by subscribing a T. We use it for *Theologiæ* &c.: as S. T. P. *Sacræ Theologiæ Professor* (Professor of Sacred Theology).——In Music, T signifies *tenor;* and *tace*, to indicate silence; it also stands for *trillo*, a shake; and in concertos and symphonies it is likewise the sign of *tutti*, a direction to the whole band to play after a solo.

TA'BARD, a kind of tunic, covering the body before and behind, reaching below the loins, but open at the sides, from the shoulders downwards; it was a usual article of dress in the middle ages: blazoned with coats of arms, it is the dress of the heralds at present.

TABASHEER' (*Persian*), a substance found in the joints of the bamboo, which is highly valued in the East Indies as a medicine; but, as it is pure silex, its utility is merely imaginary.

TAB'BY (*tabino: Ital.*), in Commerce, a thick kind of *taffeta*, watered or figured, by means of a calender, the iron or copper rolls of which are engraved. The parts engraved pressing upon the stuff occasion that inequality of the service by which the rays of light are differently reflected.——*Tabbying*, the passing of silk, mohair, or other stuffs under a calender, to give them a wavy appearance.

TABERDARS, the name of some of the scholars at Queen's College, Oxford.

TAB'ERNACLE (*tabernaculum*, a tent: *Lat.*), among the Jews, a kind of tent or movable building, placed in the middle of the camp, for the performance of religious worship, sacrifices, &c., during the wanderings of the Israelites in the wilderness; and made use of for the same purpose till the building of the temple of Jerusalem. It was of a rectangular figure, thirty cubits long, ten broad, and ten high.——*The Feast of Tabernacles*, a solemn festival of the Jews, observed after harvest, on the fifteenth day of the month Tisri; instituted to commemorate the goodness of God, who protected them in the wilderness.——*Tabernacle* is also used to signify the box in which the Host is kept on the altar in Roman Catholic churches; and for the niche or cabinet in which relics, images, &c., are preserved.

TA'BES (*Lat.*), in Medicine, a wasting of the body: emaciation: atrophy.

TABLE (*tabula: Lat.*), in Anatomy, a division of the cranium or skull.——In Arithmetic, any series of numbers, formed so as to expedite calculations, as the tables of weights and measures.——In Astronomy, computations of the motions and other phenomena of the heavenly bodies.——In the glass manufacture, a circular sheet of finished glass, usually about four feet in diameter, weighing 10 or 11lbs., twelve of which make a side or crate of glass.——In Heraldry, escutcheons containing nothing but the mere colour of the field, and not charged with any bearing, are called *tables d'attente*, tables of expectation, or *tabulæ rasæ*.——Among jewellers, a *table* diamond, or other precious stone, is that whose upper surface is quite flat, and only the sides cut in angles.——In Literature, a collection of heads or principal matters contained in a book, with references to the pages where each may be found; as, a *table* of contents.——In Mathematics, a system of numbers calculated for expediting astronomical, geometrical, and other operations: thus we say, *tables* of the Stars; *tables* of Sines, Tangents, and Secants; *tables* of Logarithms, &c.——In Religion, a division of the ten commandments; as, the first and second *tables*. The first table comprehends the laws regarding God, the second those regarding man.——*Table*, in perspective, the transparent or perspective plane.——Knights of the *round table*, a military order said to have been instituted by Arthur, the first king of the Britons, A.D. 516.——*Laws of the twelve tables*, the first set of laws of the Romans, so called, probably, because they were engraved on tables or plates of copper, to be exposed in the most public part of the forum.

TABLEAUX VIVANTS (living pictures: *Fr.*), groups of persons, so dressed and placed as to represent paintings, statuary, scenes described by poets, &c. They are usually thus managed; a frame is made of sufficient width, covered with gauze, behind which the persons stand in appropriate attitudes and costume: lamps being so placed as to reflect light on the group from above.

TABOO', a word used by the South Sea islanders to denote something consecrated, sacred, and forbidden to be touched, or set aside for particular uses and persons.

TAB'ULAR SPAR (*tabularis*, pertaining to thin plates: *Lat.*), a silicate of lime, of a grayish white colour, whose primary form is regarded as a doubly-oblique prism. Before the blowpipe it melts on the edges into a semi-transparent colourless enamel.

TACAMAHAC'A, or **TAC'AMAHAC** (*Ind.*), a resin of doubtful origin; brought from America in large oblong masses, wrapped in flag leaves; of a light brown colour, and an aromatic smell between that of lavender and musk.

TACK, the course of a ship with regard to the position of her sails; as the starboard *tack* or larboard *tack*: the wind, in the former case, being on the starboard, in the latter, on the larboard side.——*To tack*, to change the course of a ship by shifting the position of the sails from one side to the other.

TAC'KLE, the rigging, blocks, and other apparatus of a ship. Also a machine for raising and lowering heavy weights, consisting of a rope and blocks or pulleys.

TAC'TICS (*taktikos*, suited to arranging: *Gr.*), a term which, in its most extensive sense, relates to those evolutions, manœuvres and positions which constitute the main spring of military and naval finesse Tactics are the means by which discipline is made to support the operations of a campaign, and are studied for the purpose of training all the component parts according to one regular plan or system; by means of which, celerity, precision, and strength are combined, and the whole rendered effective

TADOR'NA, or **SHELDRAKE** [which see].

TAD'POLE (*tad*, a toad; and *pola*, a young one: *Sax*), a young frog, before it has assumed its adult form. [See FROG]

TÆ'NIA (*tainia*, literally a band. *Gr*), in Architecture, the lintel which separates the architrave from the frieze, in the Doric order——TÆNIA, in Natural History, the *Tape worm*, an intestinal worm infesting mammalia, reptiles, and fish. This genus of entozoa is usually found in the alimentary canal; generally at the upper part of it Tape worms are sometimes collected in great numbers, so as to occasion the most distressing disorders. Each individual is in reality a colony of several hundred in a single file. The *proglottis*, or so-called head, containing eggs which have been developed into embryos, detaches itself, and finding its way into the open fields, &c , bursts and scatters the embryos, each of which finds its way into the flesh of some animal, rendering it measled, and after being further developed, enters the body of some other animal which eats the measled meat raw, or badly cooked.

TAF'FRAIL, the upper rail of a ship's stern: being a curved piece of wood, generally ornamented with carved work.

TAL'BOT, in Sporting, a sort of hunting dog between a hound and a beagle; with a large snout, and long, round, pendulous ears. It is remarkable for the eagerness with which it finds out the haunts of game, and pursues it.

TAGLIACOTIAN OPERATION. That used for restoring the nose. Tagliacotius, a Venetian surgeon, who wrote upon it, in 1598, and proposed the formation of the new organ from a piece cut out of the shoulder or arm, is generally considered its inventor; but the operation seems to have been practised in India from the earliest times; and it was frequently employed by the Italians, but particularly the Romans—with whom the loss of the nose was often inflicted as a punishment. In modern times an artificial nose is formed with a triangular piece of skin, cut out of the forehead, and turned with its apex downwards, so as to adhere to the newly cut surface of the mutilated organ.

TALC, in Mineralogy, a well known species of magnesian earth, the colour of which is generally one of the shades of green. It consists of broad laminæ or plates; is soft and unctuous to the touch; has a shining lustre, and is often transparent. By the action of heat, the laminæ open a little, the fragment swells, and the extremities are, though with difficulty, fused into a white enamel. The Romans prepared a beautiful blue, by combining talc with the colouring fluid of particular kinds of testaceous animals. They employed it both for window lights and for the pavement of magnificent buildings; and it is still used in many parts of India and China, in windows, instead of glass. It is found in various parts of the world. In England, Northamptonshire is the district most peculiarly known for this production; and it is met with in the northern parts of Scotland

TAIL, or **FEE-TAIL** (*tailler*, to prune *Fr.*), in Law, an estate or fee limited to a person, and the heirs of his body, general or special, male or female; opposed to fee-simple [See FEE and ENTAIL.] The estate, provided the entail be not barred, reverts to the donor or reversioner, if the donee die without proper heirs,

TAL'ENT (*talanton*, literally, a thing weighed: *Gr*), among the Ancients, the name of a Grecian weight, of different amounts; but usually about half a hundred ——Also, a sum of money, the true value of which cannot well be ascertained: but it is known that it was different among different nations. Among the Hebrews, there was both a talent of gold and a talent of silver, the former was worth 5,475*l.*; the latter, 342*l.* 3*s.* 9*d* The Attic talent, that most commonly used by the Greeks, is supposed to have been worth 243*l.* 15*s.* The *greater* talent of the Romans was worth 99*l.* 6*s* 8*d.*; and the *less* 60*l.*, or as some say 75*l.* Their *great* talent was equivalent to 1,125*l.*

TA'LES, in Law; if, when proceeding to the trial of a cause by a special jury, there are not a sufficient number of special jurors present, either party may pray a *tales;* that is, may ask the judge to allow a sufficient number of qualified men, who happen to be present (tales de circumstantibus) to be joined with the jurors, so as to make up the number of twelve.

TAL'ISMAN, a word of Arabic origin, signifying a figure cast or cut in metal or stone; and made, with certain superstitious ceremonies, during some particular configuration of the heavens; as when planets are in conjunction; and supposed to have extraordinary influence in averting disease. But, in a more extensive sense, the word *talisman* is used to denote any object in nature or art, the presence of which checks the power of spirits or demons, and defends the wearer from their malice. The talisman seems to differ from the *armlet*, in the more extensive power attributed to it.

TAL'LOW, the suet of the ox and sheep, melted and strained, to separate it from the membrane. It is a most important article, in commerce. The drier the food on which the animals are fed, the more solid is the tallow; hence the Russian is the best; as the animals whence it is obtained are, in that country, fed for eight months of the year on dry fodder. It consists of carbon, hydrogen, and some oxygen. [See FAT.] Besides the large quantity of tallow produced in this country, we imported, in 1858, 1,235,789 cwt., the value of which was 3,042,381*l.*

TAL'LOW-TREE, the *Stillingia sebifera*, nat. ord. *Euphorbiaceæ*, a remarkable tree growing in great plenty in China; so called from its producing a substance like tallow, applicable to the same purposes. The tallow-tree is about the height of the cherry-tree; the foliage resembles the Lombardy poplar; and at the end of the season the leaves turn bright red. The fruit, which is enclosed by a kind of coat resembling that of a chestnut, is composed of three grains, of the size and form of a small nut. The capsules and seeds are crushed together and boiled; the fatty matter is skimmed as it rises, and condenses on cooling. The candles made of this substance are very white.

TAL'LY (*tailler*, to cut: *Fr.*), a mode of reckoning between buyers and sellers, which before the use of writing was almost universal, and which is even still partially used. The *tally* is a piece of wood on which notches or scores are cut as marks of number. It is customary for traders to have two of these sticks, or one stick cleft into two parts, and to mark or notch them in a corresponding manner; one to be kept by the seller, the other by the purchaser.——In the English exchequer, tallies have been abolished, and the old ones have been destroyed.

TAL'LY TRADE, the name given to a system of retail trade, by which shopkeepers furnish certain articles on credit to their customers, the latter agreeing to pay a stipulated sum weekly.

TAL'MUD (*lamad*, he taught: *Heb.*), the interpretations of the Law of Moses, given by the Rabbins, and valued by many of the Jews even more than the Law itself. There are only two Talmuds, those of Jerusalem and Babylon; the former printed in one volume folio, and the latter in fourteen. The works of Jonathan and Onkelos are to be considered as paraphrases rather than interpretations. The Talmud of Jerusalem consists of two parts, the *Mishna* (a reiteration: *Heb.*), drawn up by Rabbi Juda Hakkadosh, 120 years after the destruction of the Temple of Jerusalem: and the *Gemara* (a finishing: *Chald.*), the work of Rabbi Johanan, the rector of a school at Tiberias about 100 years later. The Mishna is more correct than the Gemara, which is filled with dreams and foolish disputations. The Talmud of Babylon, which is of higher authority among the Jews than that of Jerusalem, was composed by Rabbi Aser, who kept an academy for 40 years at Sara near Babylon; he did not live to finish it, but it was completed by his disciples about 500 years after Christ. Enormous quantities of Talmudic works were committed to the flames by popes Gregory IX., Paul IV., and Clement VIII., under pretence of their being erroneous productions.

TAL'ON, in Architecture, a kind of moulding, which consists of a cymatium, crowned with a square fillet. It is concave at the bottom, and convex at the top: and is usually called by workmen an *ogee*, or O G.

TAL'PA (a mole: *Lat.*), in Surgery, a tumour under the skin or cuticle, usually called a mole.——In Zoology, the *Mole*, which see.

TA'LUS (*Lat.*), in Anatomy, the *astragalus*, one of the bones of the ankle.——In Geology, the accumulation of fragments at the foot of a steep rock, more or less filling up the angle.——In Fortification, the slope of a work, as that of a bastion, rampart, or parapet.

TAM'ARIND (*tamar-hindy*, Indian date: *Arab.*), large leguminous trees, growing in the East and West Indies, from the pods of which is obtained a well-known subacid confection.

TAM'BOUR (a drum: *Fr.*), a species of embroidery wrought on a kind of cushion or spherical body, stretched on a frame, so that it somewhat resembles the head of a drum, or a tambourine. A frame of a different construction is used when several workers are employed on the same fabric; it consists principally of two rollers, which, when properly fixed, stretch the material to the necessary degree of tension. But machines of extraordinary ingenuity have of late years been constructed for tambour-working, by which the greatest accuracy is ensured, while the saving of manual labour places them among those efforts of mechanical skill which are the distinguishing features of the present age.——*Tambour*, in Architecture, the wall of a circular building, surrounded with columns.——In Mechanics, the cylindrical axle-tree of a wheel, which serves to draw up stones out of a quarry.——*Tambour*, in Fortification, a kind of work formed of palisades or pieces of wood ten feet long, planted close together, and driven firm into the ground.

TAMBOURI'NE (*tambourin: Fr.*), one of the most ancient musical instruments. It is still used in the Basque provinces, where a large kind, called *tambour de Basque*, is played as an accompaniment to all the national songs and dances. In Scripture, this instrument is designated a *timbrel;* in profane history we find it was popular among most of the Eastern nations; and in the middle ages it was used by the Troubadours and minstrels. The present tambourine consists of a wooden or brazen hoop, over which a skin is extended, and which is hung with a kind of bells. Sometimes the thumb of the right hand is drawn in a circle over the skin; sometimes the fingers are struck against it; while it is supported by the thumb of the left hand.

TAM'POE, an East Indian fruit somewhat resembling an apple.

TAN (*tann*, the oak: *Armor.*), the bark of the oak, or other tree ground or chopped; and used in tanning leather. Tan after having been employed in tanning, is used in gardening, for making hotbeds.

TAN'GENT (*tangens*, touching: *Lat.*), in Geometry, a straight line which touches a curve, but which, when produced, does not cut it.——In Trigonometry, the tangent of an arc is a right line touching the arc at one extremity, and terminated by a secant, or radius produced, passing through the other extremity.

TAN'ISTRY, an old tenure of lands in Ireland, &c., by which the proprietor had only a life estate, and the inheritance descended to the oldest or most worthy of the blood and name of the deceased; but the practice often gave rise to the fiercest and most sanguinary contests between tribes and families.

TANNIC ACID, in Chemistry, a substance obtained by acting with ethers upon bruised galls. It is a white amorphous powder, scarcely soluble in water, which reddens litmus paper. When moistened and exposed to the air it becomes *gallic acid* by the absorption of oxygen. It is a compound of carbon, hydrogen, and oxygen. It is very astringent, and seems to be the active principle of tanning substances in general.

TAN'NIN, in Chemistry, the pure astringent principle of vegetables; and that which gives them the power of changing skin into leather. It may be obtained by adding acetate of copper to filtered infusion of galls, and wasting the precipitate: then diffusing it through water, and decomposing it by sulphuretted hydrogen; a pale yellow extract, of a strong astringent taste, is obtained by evaporating the solution: this is *tannin*. It produces a dense white precipitate in a strong solution of an animal jelly, isinglass for example. The tannin of galls, bark, grape-seeds, &c., precipitates the persalts of iron blue or black; that of catechu and tea precipitates them green. The skin of an animal when freed from the hair, epidermis, and cellular fibre, consists chiefly of indurated gelatine. By immersion in the tan-liquor, which is an infusion of bark, the combination of tannin with the organized gelatine, which forms the animal fibre, is slowly established; and the compound of tannin and gelatine not being soluble in water, and not liable to putrefaction, the skin is rendered dense and impermeable, and not subject to the spontaneous change which it would otherwise soon undergo.

TAN'NING, the art or process of preparing leather from the raw hides of animals, by means of tan. After being cleared of the hair, wool, and fleshy parts by the help of lime, scraping, and other means, the hides are macerated in an astringent liquor, formed from the bark of the oak. This is usually done by putting into the tan-pit layers of ground oak-bark and skins alternately, with the addition of a small quantity of water. The process is long and laborious: requiring from seven to twelve months; and, in the case of buffalo hides, eighteen, or even twenty-four. But it has been greatly accelerated by carrying it on *in vacuo;* the air being rarified, the pores of the skins are opened, and more readily absorb the tanning principle; also the tannic acid is not so easily changed in gallic, which is an advantage. If the skins are kept in motion they are tanned *in vacuo* in from four to forty days; the latter being sufficient for the best ox-hides, which by the old process would require probably twelve months, or about nine times as long; but some believe the best leather to be produced by the old mode of manufacture.

TAN'SY the *Tanacetum vulgare* of botanists; a British wild plant of the nat. ord. *Compositæ*. It has small yellow flowers, like buttons, disposed in a large upright corymb. The whole plant has a strong and penetrating odour, and an extremely bitter taste. It contains an acrid volatile oil, and is used in medicine as a stimulant and carminative.

TAN'TALITE, in Mineralogy, the ferruginous oxide of columbium, called also *columbite*. It is found in small masses, and octohedral crystals, in Finland and the United States.

TAP'ESTRY (*tapisserie: Fr.*), a curious production of the loom, in which the finest pictures may be represented. It consists of a kind of woven hangings of wool and silk, often enriched with gold and silver, representing figures of men, animals, landscapes, historical subjects, &c. This species of covering for walls was known among Eastern nations from a very remote era; but it is supposed that the English and Flemish, who were the first that, in the northern parts of the world, excelled in this art, learned it from the Saracens during the crusades. During the 15th and 16th centuries the art was practised with great skill at Arras, in Flanders; and tapestries were executed there after the masterly designs of Raphael, termed his *cartoons*. These were originally thirteen in number; and seven of them are in the South Kensington Museum, London. Copies of them, in tapestry, were executed by order of Leo X., and cost 7,000 crowns in gold. The manufacture was carried on in England, and much patronized; but this kind of decoration has long since given place to paper, &c. Colbert, the celebrated minister of Louis XIV., established *Gobelin's* celebrated manufactory of tapestry, in the neighbourhood of Paris. [See GOBELINS.]

TAPIO'CA. [See MANIOC and CASSADA.]

TA'PIR, in Zoology, a genus of pachydermatous quadrupeds, of which there are three existing, and several extinct species. They have a short proboscis, four toes on the fore foot, and three on the hind foot. One species inhabits Sumatra, Malacca, and some of the surrounding countries. The two other species are natives of South America. The *Tapir Americanus* is about six feet long and upwards of three feet high It shuns the habitations of man, and leads a solitary life in the interior of forests, living on fruits and the young branches of trees. When domesticated, it eats every kind of food. Though possessed of great strength, it uses it only for defence; and its disposition is mild and timid.

TAR, a dark-brown viscid liquid, obtained by the destructive distillation of wood of the fir-tree; it consists of resin, empyreumatic oil, and acetic acid; and is converted into pitch by boiling. Six different substances have been obtained from it, *paraffine*, *eupion*, *creasote*, *picamar*, *capnomar*, and *pittacal*. The more liquid species of bitumen are also called *mineral tar*.

TARAN'TULA (from *Tarentum*, in Italy), the *Lycosa tarantula*, the largest of European spiders, the bite of which produces symptoms formerly supposed to be curable only by music. The name of the *tarantella*, the national dance of Sicily, is derived from it.

TARE, in Commerce, an allowance for the outside package, that contains such goods as cannot be unpacked without detriment; or for paper, bands, cord, &c. When the tare is deducted, the remainder is called the *net* or *neat* weight.

TAR'GUM (*Heb.*), a name given by the Jews to certain glosses and paraphrases of the Scriptures, composed in the Chaldaic language. The two principal Targums on the greater and lesser prophets, except Daniel, Ezra, and Nehemiah, were written by Jonathan, or rather Pseudo-Jonathan, about thirty years before Christ; that of Onkelos, on the Pentateuch, is supposed to have been written in the first century of our era. There are eight others: two of which are considered of great antiquity.

TAR'IFF, or TAR'IF (*tarif: Fr.*), in Commerce, a list or table of custom-house and excise duties imposed on goods, with their respective rates.

TARPE'IAN, in Roman Antiquity, an appellation given to a steep rock in Rome; whence, by the law of the twelve tables, those guilty of certain crimes were precipitated. It was named after Tarpeia, the daughter of Tarpeius, the governor of the citadel of Rome, who, as the tradition runs, promised to open the gates of the city to the Sabines, provided they gave her their gold bracelets, or, as she expressed it, what they carried on their left hands. The Sabines consented, and, as they entered the gates, threw not only their bracelets, but their shields, upon Tarpeia, who was crushed under the weight. It has been much reduced in height by the ruins which have accumulated for ages at its base.

TAR'RASS, or TER'RAS, in Mineralogy, a volcanic earth, resembling puzzolana, used as a cement. The Dutch tarras is made of a soft rock stone found near Collen, on the lower part of the Rhine. It is burnt like lime, and reduced to powder by being ground.

TAR'SUS (*tarsos*, the flat of the foot: *Gr.*), in Anatomy, a part of the human foot, the front of which is called the instep. There are seven bones in two rows.——In Birds, the term is sometimes applied to the third segment of the leg, which is seldom covered with flesh or feathers; it corresponds with the tarsus and metatarsus conjoined.——In Insects, it is the collection of minute joints, which make up the fifth principal segment of the leg or foot. *Tarsus* is also used by some for the cartilages which terminate the *palpebræ*, or eyelids, and from which the *cilia* or hairs arise.

TAR'TAR, an impure tartrate of potash deposited by grape juice in the act of fermentation. In its crude state, it is much used as a flux in the assaying of ores. When purified it is called Cream of Tartar. [See ALGOL.]

TAR'TAR EMETIC, in Chemistry, a double salt, consisting of tartaric acid combined with potash and protoxide of antimony.

TARTAR'IC ACID, in Chemistry, an acid composed of carbon, hydrogen, and oxygen, which exists in grapes, pine apples, and other fruits. The acid of commerce is prepared from *tartar* or *algol*.

TAR'TARUS (*Lat.*), a region of hell, where the Greeks and Romans supposed the most wicked of men were punished after death. A dark cloud concealed the entrance, a brazen wall surrounded it, or, according to Virgil, three walls and the burning river Phlegethon. It was here that the great criminals of mythology Ixion, Tityus, the daughters of Danaus, Tantalus, Sisyphus, and others, underwent their punishment.

TAR'TRATES, salts formed by the combination of tartaric acid with different bases; as *tartrate* of potash, *tartrate* of soda, &c.

TASTE, in Physiology, one of the five senses; a peculiar sensation excited by means of the nervous papillæ of the tongue. ——*Taste* is also used, in a figurative sense, for the judgment and discernment of the mind, regarding what is grand and beautiful both in art and nature. Taste is, in some degree, the fruit of observation and reflection—not wholly the gift of nature, nor wholly the effect of art.

TATTOO' (*tapotez tous*, tap, all of you: *Fr.*), the beat of the evening drum, giving notice to soldiers to repair to their quarters in garrison, or to their tents in camp.

TATTOO'ING, a mode of marking the skin of the face, back, breast, arms, and legs, with ineradicable stains arranged in curved or straight lines, adopted by the South Sea Islanders, the New Zealanders, and the Red Men of tropical America. A pointed instrument is employed to perforate the skin, and then the colouring matter is applied.

TAUROBO'LIUM (*tauros*, a bull; *bollo*, I slaughter: *Gr.*), an altar whereon a bull was solemnly sacrificed to Cybele, the mother of the gods, out of gratitude for the preservation of the Emperor of Rome. It usually consisted of a cubical block of stone surmounted by a cornice and ornamented with sculptures, amongst which a bull's head often appeared. These altars are frequently exhumed in countries occupied by the Romans.

TAU'RUS (*Lat.*), in Astronomy, the *Bull*, the second of the twelve zodiacal constellations and signs. It contains several very remarkable stars, *Aldebaran*, of the first magnitude in the eye, the cluster, called the *Pleiades*, in the neck, and the *Hyades*, in the face.

TAUTOCHRONE (*tauto*, just the same; and *chronos*, time: *Gr.*), in Mechanics, the curve upon which a heavy body, acted upon by gravity, will descend so as to arrive at the lowest point in the same time from whatever point it begins to move. Huygens showed that, in a vacuum, the curve is a cycloid. Gravity being supposed to act in parallel straight lines, Newton showed it to be a cycloid in a resisting medium also, when the resistance is proportional to the *velocity;* and Euler determined its nature when the resistance is proportional to the *square of the velocity*.

TAWING, the preparation of white leather, by impregnating skins with saline, oily, and other matters; it differs from tanning, in which they are combined with astringent principles. [See TANNING.]

TAXES (*taxo*, I estimate: *Lat.*), the assessments imposed by Law for the public service: either *direct*, as on persons and necessaries; or *indirect*, as on luxuries and raw materials. Taxes imposed on goods at the time of their importation, are denominated *customs*, *duties*, or *imposts*. In imposing taxes, a government should keep certain great principles in view.—The subjects of a state should contribute to its support, and in proportion to their respective abilities. The amount of a tax and the time of payment should not be arbitrary, but fixed and well known. Every tax should be levied at the time, and in the manner, likely to be most convenient to him who pays it; and it should be collected at as small an expense as possible. Taxes on commodities are either *external*, that is, paid on the frontier; or *internal*, that is, excise duties. *Land tax* is another source of revenue: *stamp duties* and assessed taxes are others. In Great Britain, the taxes are almost entirely collected by government officers, paid by regular salaries. In 1858, the revenue was 60,850,060*l.*, or about 41*s.* 2*d.* per head: namely, customs, 24,155,852*l.*; excise, 18,480,572*l.*; stamps, 8,247,342*l.*; and assessed taxes, including income tax, 9,975,294*l.*: being, on account of the Russian war, about nine millions in excess of the average revenue for the preceding ten years. To this must be added about 15,000,000*l.* for poor rates and other local taxations; the real property in Great Britain and Ireland being estimated at 3,200,000,000*l.*; and the personal, at 2,775,000,000*l.*

TAX'IDERMY (*taxis*, an arranging; and *derma*, the skin: *Gr.*), the art of preparing and preserving specimens of animals.

TAX'IS (an arranging: *Gr.*), in Surgery, an operation by which those parts which have left their natural situation are replaced by the hand, without the assistance of instruments; as in reducing hernia, &c.

TEA, the dried leaves of Chinese shrubs belonging to the genus *Thea*, nat. ord. *Ternstrœmiaceæ*. They are natives of China, Japan, and Tonquin, flourishing most in valleys, the sloping sides of mountains, and the banks of rivers exposed to the southern rays of the sun. There are two species of the tea plant, *Thea viridis*, with broad leaves, and *Thea bohea:* the former being considered by some as the source of green, and the latter of black tea. There is also a variety, termed *Thea Assamensis*, which seems to resemble both the others. The names given in commerce to the different sorts of tea are unknown to the Chinese, the imperial excepted, and are supposed to have been applied by the merchants of Canton. The black teas are, Bohea, Congou, Campoi, Souchong, Caper, and Pekoe; the green teas are Twankay, Hyson skin, young Hyson, Hyson, Imperial, and Gunpowder. The quality of tea depends very much on the season in which the leaves are picked, the mode in which it is prepared, and the district in which it grows. Green tea is said to owe its colour to an extract of indigo, to Prussian blue, and gypsum; and the *flowering kinds* their rich tint to the leaves of the *Olea fragrans* and other plants. The most remarkable substances in teas are tannin, an essential oil to which it owes its aroma, and an alkaloid named *theine*. 100 parts of dried tea contain, on an average, about 6 parts nitrogen; the largest amount, by far, that has been detected in any vegetable. Tea, taken in moderation, is beneficial to the body; but in most constitutions, if taken in excess, it produces considerable excitement and wakefulness. Tea and coffee owe their energy to two substances, *Theine* and *Caffeine*, which differ in name, but are identical in nature. The tea plant is the growth of a particular region, situated between the 30th and 33rd degrees of north latitude. The trees are planted four or five feet asunder; they have a very stunted appearance, and are not allowed to grow higher than is convenient for men, women, and children to pick the leaves. When this is done, the leaves are put into wide shallow baskets, and placed on shelves in the air, wind, or mild sunshine, from morning till noon. They are then placed on a flat cast-iron pan over a charcoal stove, ten or twelve ounces being thrown on at a time, and kept stirred quickly with a hand-broom. After this, they are brushed off again into the baskets, in which they are equally and carefully rubbed between men's hands to roll them; and then are again dried over a slower fire. The tea is next laid upon a table to be drawn or picked over. The smallest leaves are called by the Chinese *Pha-ho;* the second, *Pow-chong;* the third, *Su chong;* and the fourth, or largest, *Tay-chong*. In 1863, tea to the amount of 136,806,319 *lbs.* was imported, of the value of 10,666,017*l.*, and of this 85,206,769 *lbs.* were entered for home consumption.

TEAK'-TREE, the *Tectona grandis*, one of the largest trees known, although it belongs to the same order as the lowly verbenas of our gardens; it may be regarded as the oak of the Eastern world, and the only Indian wood impenetrable by white ants. It is, in many respects, superior to oak; without fear of dry or wet rot, it may be used almost green from the forest; it is capable of enduring all climates, and all alternations of climate. It is strong, light, and easily wrought at all ages; and is much used in building ships as well as houses. This tree abounds in the extensive forests of Java, Ceylon, Malabar, Coromandel, &c., but especially in the empires of Birmah and Pegu, from which countries Calcutta and Madras draw all their supplies of ship timber. The teak of Malabar, produced on the high table-land, to the south of India, is deemed the best. There is a species of timber, called African teak, largely imported into England; but it belongs to the order of *Euphorbiaceæ*, and it is destitute of several of the most valuable properties of the true teak.

TEARS, the limpid fluid secreted by glands adjoining the eye, and increased by emotions of the mind, but more especially by grief. This fluid is also called forth by any injury done to the eye. It consists of about one per cent. solid matter; composed of common salt with traces of phosphate of soda, and albumen. This fluid serves to moisten the cornea and preserve its transparency, as well as to remove any dust or other substance that enters the eye. The lachrymal glands are the organs which secrete this liquid; one of them is situated in the external canthus of each orbit, and emits six or seven excretory ducts, that open on the internal surface of the upper eyelid, and pour forth the tears.

TECHNOL'OGY (*technē*, an art, and *logos*, a discourse: *Gr.*), a treatise on the arts; or an explanation of the terms of the arts. A *technical* word is a word that belongs properly or exclusively to the arts.

TE DE'UM, the title of a celebrated hymn used in the Christian church, and so called because it begins with the words, *Te deum laudamus*; We praise thee, O God. It is sung in the Roman Catholic churches with great pomp and solemnity, on occasions of joyful thanksgiving.

TEETH, the bony organs with which vertebrate animals seize or prepare their food. In the higher mammals, a tooth is composed of three tissues, viz. DENTINE, which forms the body of the tooth; *cement*, which forms the outer crust; and *enamel*, which is placed between the dentine and the cement. The cement resembles in texture the bones of the same animal, and in adult man it is confined to the outer part of the fangs. The enamel is the hardest of the dental tissues, and, like the others, consists of earthy matters deposited in minute cells. The typical number of teeth in the mammalia is 44 (the hog for example having this number), but the average one of that class is 32, as we find in man, the old world apes, and the true ruminants. In each of the jaws of the adult man are four cutting teeth, or *incisors*, in front, followed on each side by one canine tooth and five grinding teeth, or *molars*, of which the two next the canine tooth are termed *premolars*. All the teeth except the true molars are shed early in life, and are replaced by others which grow up from beneath them. The first set of teeth are denominated temporary deciduous or milk teeth. The method adopted by anatomists for expressing the number and kind of the teeth, may be thus illustrated by the dental formula of man:

$$i\,\frac{2-2}{2-2}\quad c\,\frac{1-1}{1-1}\quad p\,\frac{2-2}{2-2}\quad m\,\frac{3-3}{3-3}=32$$

where the letters indicate the names of the teeth as given above, and the numbers above and below the lines respectively indicate the teeth in the upper and lower jaws, whilst the short lines separating the figures serve to point out the different sides of the jaws. The teeth of different animals vary greatly in shape according to the uses to which they are applied. Take the molar teeth, for example. Amongst the true carnivora they are compressed laterally, and have sharp cutting edges, which shut like the blades of scissors, one set over the other. By this structure these animals are able to divide their food with great facility. The insectivora, such as the mole and bat, have molars terminated by several sharp points. Herbivorous animals have the summits of their molars flat with prominent ridges, a structure that enables them to crush and triturate their food. An omnivorous animal like man has several rounded tubercles on the grinding surfaces. From this variety in the shapes of teeth, and the constancy of their correspondence with the structure of the body, it happens that a single molar will always indicate the group to which any animal belongs.

TEETH OF WHEELS, those prominent portions in the peripheries of wheels which, locking in each other, convey the power of a prime mover to the working parts of machinery. They should be of such a shape as to roll and not slide on each other, should have such a curvature as that the angular velocities of the two pieces working together shall preserve the same constant ratio, in all positions of contact. To secure this condition it is necessary that the acting faces of the teeth shall have such a shape that the normal common to the two surfaces in contact, shall always divide the *line of centres* in a fixed point. Many forms would effect this, but a few only are actually employed.

TEE-TOTALLERS. [See TEMPERANCE SOCIETIES.]

TEL'EGRAPH (*tēle*, far off; and *grapho*, I write: *Gr.*), a machine for communicating intelligence to a great distance, by various signals or movements previously arranged. The conveyance of information by signals was practised from the earliest ages; but a telegraph universally applicable was first described by Hooke in 1684; it was not, however, put into practice, nor was telegraphic communication applied to any useful purpose until 1794, when it was used to convey intelligence to the French armies. The method consisted in a beam, which turned on a pivot in the top of an upright post, having a movable arm at each of its extremities; and each different position, in which the beam and its two arms could be placed at angles of 45°, afforded a separate signal, which might represent a letter of the alphabet, or anything else agreed upon. Many modifications of the telegraph were invented successively in this country, &c., but they have all been superseded by that admirable contrivance, the electric telegraph, which see.

TEL'ESCOPE (*tēle*, far off; and *scopeo*, I view: *Gr.*), an optical instrument employed in viewing distant objects. It assists the eye chiefly in two ways; first, by enlarging the visual angle under which a distant object is seen, and thus magnifying that object; and, secondly, by collecting and conveying to the eye a larger beam of light than would enter the naked organ, and thus rendering objects distinct and visible, which would otherwise be indistinct or invisible. Telescopes are either *refracting* or *reflecting;* the former consist of different lenses through which the objects are seen by rays refracted by them to the eye, and the latter consist of specula from which the rays are reflected and passed to the eye. The lens turned towards the object is called the *object-glass;* that to which the eye is applied, the *eye-glass;* and if the telescope consist of more than two lenses, all but the *object-glass* are called *eye-glasses.* It was not till the middle of the 16th century (1549), that the application of glasses to this instrument was made. In fact, no advances were made in the construction of telescopes before the time of Galileo, who, while at Venice, accidentally heard that a sort of optic was made in Holland, which brought distant objects nearer; and considering how this thing might be, he set to work and ground two pieces of glass into a form, as well as he could, and fitted them to the two ends of an organ pipe, with which he produced an effect that delighted and astonished all beholders. After exhibiting the wonders of this invention to the Venetians on the top of the tower of St. Mark, he devoted himself wholly to the improving and perfecting the telescope, in which he was so successful that it has been usual to give him the honour of being the inventor.——REFRACTING TELESCOPES. The *Galilean telescope* consists of a convex converging object-glass, and a concave diverging eye-glass. Its magnifying power is equal to the focal length of the object-glass divided by the focal length of the eye-glass; the length of the tube is the difference between the focal lengths of the lenses. It causes an object to be seen erect, and its principle is applied in the opera glass, for which purpose its magnifying power is rarely greater than 4, and often as low as 2.——The *astronomical telescope* consists of a converging object-glass and a converging eye-glass. Its magnifying power is equal to the focal distance of the object-glass, divided by the focal distance of the eye-glass; the length of the tube is the sum of the focal distances of the lenses. It causes the object to appear inverted.——The *terrestrial telescope* differs from the astronomical, in having two additional lenses in the tube of the eye-glass, for the purpose of rendering the inverted image erect.——REFLECTING TELESCOPES. In these, the speculum or mirror performs the same office as the object-glass in refracting telescopes, and is called the *object mirror.* They were invented by Gregory, and described by him in 1663, but were first used by Newton. The *Newtonian telescope* consists of a tube, at the end of the interior of which is a speculum, which exactly fits it; the rays from the object, entering the open end of the tube, are reflected back in a convergent state to a small diagonal speculum which throws them out through an aperture at the side of the tube, not far from its open end. The small diagonal speculum is intended to prevent the necessity of the observer looking down into the tube, and thus intercepting a large quantity of light from the object. The magnifying power is equal to the focal length of the object mirror, divided by that of the eye-glass which is used.——The *Gregorian telescope* resembles the last, except that the small mirror is not placed diagonally but transversely, so as to throw the rays back through an opening in the centre of the object mirror; after forming an image which is viewed by an eye-piece, when the rays have passed through the aperture. The magnifying power is obtained in the same way as with the Newtonian telescope, and the image is erect.——The *Cassegranian telescope* resembles the Gregorian, except that the small mirror is convex instead of concave; it requires a shorter tube, but the image is inverted.——The *Herschelian telescope* requires no second speculum; and thus a loss of light by second reflection is avoided. The object mirror, which has no perforation, is placed at the end of the tube in an inclined position, so as to bring the focal image near the edge of the tube, where, without interfering with the light entering the telescope, it is viewed by an eye-piece; the image is, however, slightly injured by the oblique reflection. The magnifying power is formed in the same way as with the Newtonian telescope. Herschel's gigantic telescope, erected at Slough, near Windsor, was completed August 28, 1789; and on the same day the sixth satellite of Saturn was discovered. The diameter of the polished surface of the speculum was 49½ inches, its thickness 3½ inches, and its weight when cast 2,118lbs.; its focal length was 40 feet, and it admitted a power of 6450 to be applied to it. Such large telescopes collect immense quantities of light, which enable the observer to perceive objects quite invisible with smaller instruments. The tube of this telescope was of iron, 40 feet in length, and upwards of 4 feet in diameter. *Lord Rosse's telescope* at Birr Castle, in Ireland, is yet more stupendous. It has two object mirrors of six feet diameter, and 53 feet focal length. Its tube is of wood upwards of 50 feet in length, and more than 6 feet in diameter; refracting telescopes also, of great magnitude, have been recently constructed. In that at *Pulkova*, near St. Petersburgh, the object-glass has a clear aperture of nearly 15 inches, and its focal length is 22½ feet.

Among the eye-pieces belonging to this telescope, there are powers as high as 2000. There are telescopes of very great power at Cambridge, near Boston, U.S., and at Cambridge in England.

TELLU'RIUM (*tellus*, the earth: *Lat.*), a metal found in very small quantities, in the metallic state, combined with gold and silver, in the gold mines of Transylvania. It is white, brilliant, brittle, and easily fusible. Its spec. grav. is about 6·25: it is combustible; with oxygen, it forms *tellurous*, and *telluric acids;* and with hydrogen, *hydrotelluric acid.*——*Tellurium*, a machine for the illustration of the motions and phenomena of the earth.

TEM'PERAMENT (*temperamentum;* from *tempero*, I proportion duly: *Lat.*), that peculiarity of organization which in some measure influences our actions, thoughts, and feelings. The ancients distinguished four temperaments—the *Choleric* or *Bilious*, the *Phlegmatic*, the *Melancholic*, and the *Sanguineous;* which derived their names from the supposed excess of imaginary fluids in the human body. To these, some have added the *Nervous.*——*Temperament*, in Music, the accommodation or adjustment of the imperfect sounds, by transferring a portion of their defects to the more perfect ones, to remedy in part the false intervals of instruments of fixed sounds, as the piano, organ, &c. The necessity for temperament arises from the interval of a tone not being always the same; for example, that lying between the fourth and fifth of the scale, contains nine small parts termed commas, while that between the fifth and sixth of the major scale contains only eight commas. The diatonic semitone contains five commas; the chromatic, three or four according to the magnitude of the tone; and the different situations of these elements, with regard to each other, causes intervals of the same name to consist of different degrees. They are *tempered*, by reducing the whole, more nearly to mean distances from each other.

TEM'PERANCE SOCI'ETIES (*temperantia*, moderation: *Lat.*). The evils of intemperance had long been the subject of much anxious observation, not merely in Great Britain, but elsewhere, more especially in the United States, and the idea of concentrating public sentiment upon it, in some form, to produce important results, seems to have been first conceived there: a meeting, called the General Association of Massachusetts Proper, having been held in 1813, for the express object of 'checking the progress of intemperance.' The first attempt of the society was to collect facts towards a precise exhibition of the nature and magnitude of the existing evil, with the view of drawing public attention to it, and of directing endeavours for its removal. The reports presented, from year to year, embraced statements and calculations which were found to make out a case of the most appalling nature, such as to amaze even those whose solicitude on the subject had been greatest. In 1830, from data carefully collected, the Massachusetts society stated in their report, that the number who died annually victims of intemperance was estimated at above 37,000; and that 72,000,000 gallons of distilled spirits were consumed in the country, being about six gallons, on an average, for every man, woman, and child of the whole population. It also stated that about 400,000 of the community were confirmed drunkards; and that there appeared reason to believe that intemperance was responsible for four-fifths of the crimes committed in the country, for at least three quarters of the pauperism existing, and for at least one third of the mental derangement. By these exposures, and an unrelaxing perseverance in the course they had commenced; by the circulation of tracts and the addresses of travelling agents; by the formation of auxiliary associations, and by obtaining individual responsibility, for the performance of a variety of duties tending to promote the great object in view, public notice was attracted, and it led to an imitation of the practice in Great Britain and Ireland. The basis on which these associations have been formed, at least in the outset, has been that of an engagement, on the part of each member, to abstain from the use of distilled spirits, except for medicinal purposes; and to forbear to provide them for the entertainment of friends or the supply of dependents. But of late years new societies have sprung into existence, whose practice of temperance is yet more strict; and they accordingly pledge themselves to a total abstinence, not from ardent spirits only, but from all wines and fermented liquors. This class is known by the name of *Tee-totallers.* Some years since, a great movement was made in Ireland by Father Mathew in favour of temperance.

TEM'PERATE ZONE (*temperatus*, moderate: *Lat.*), in Geography, the space on the earth between the tropics and the polar circles: where the heat is less than in the tropics, and the cold less than in the polar circles. The *north temperate zone* reaches from the tropic of Cancer to the Arctic circle, and the *south temperate zone* from the tropic of Capricorn to the Antarctic circle. Each has a breadth of 645 miles.

TEM'PERATURE (*temperatura*, proportion: *Lat.*), in Physics, a definite degree of sensible heat, as indicated by the thermometer; or the constitution of the air according to the diversity of the seasons or difference of climate, &c. The annual variation of heat is inconsiderable between the tropics, and becomes greater and greater as we approach the poles. This arises from the combination of two causes; namely, the greater or less directness of the sun's rays; and the duration of their action, or the length of time from sunrise to sunset.

TEM'PEST (*tempestas: Lat.*), a storm of excessive violence. [See STORMS.]

TEM'PLARS, or KNIGHTS OF THE TEMPLE, a military order of religious, established at Jerusalem, A.D. 1118, for the protection of pilgrims travelling to the Holy Land. During nearly six hundred years this order maintained an important character in Europe. In every nation it had a particular governor, called *master of the Temple*, or of the *militia of the Temple*. Its riches became immense; a fact which, among many others, justifies the observation of Raynal, that persons who have laid down rules for religious societies have done so with the sole view of making holy men; but that they have laboured more directly and more effectually to make rich ones. Towards the beginning of the fourteenth century, the Templars were charged with leaning to Mohammedanism, and, in consequence, the order was abolished under pope Clement V., Edward II. of England, and Philip the Fair of France. In 1307, all the members in England were arrested, and of these, seven suffered at the stake. In 1312, their final suppression was effected by the council of Vienna, by the direction of which fifty others of these persecuted men suffered death in the flames. The vast estates of the order fell partly into the hands of the sovereigns of the countries in which they were situated, and partly into those of the Hospitallers and other military orders. In the thirteenth century, it possessed 9,000 lordships, &c. The charges of heresy, idolatry, &c., preferred against them were not supported; the real causes of their destruction were, most probably, their arrogance and enormous wealth.

TEM'PLE (*templum*: *Lat.*), an edifice dedicated to some deity. The word is generally confined to buildings erected for heathen worship; with the exception of that at Jerusalem, called *the temple*. The earliest temples were merely an open spot, with a rude altar of earth and stones; or an enclosure like that of *Stonehenge*. The Egyptian temples were remarkable for massive dimensions, the cell, however, being always small. Those of Greece were of the most magnificent description, and were the examples after which the Romans erected theirs. The temples of Greece and Rome have been classed by Vitruvius into those *in antis*, the *Prostyle*, *Amphiprostyle*, *Peripteral*, *Dipteral*, *Pseudodipteral*, and the *Hypæthral* [see these terms].——The *Temples* in London are two inns of court, so called because anciently the dwellings of the Knights Templar. They are called the Inner and the Middle Temple, and are situated near the Thames. In ancient times there was a third called the Outer Temple, which no longer exists. On the suppression of the order of Knights Templar, the pope granted their forfeited property to the Knights Hospitaller of St. John of Jerusalem, who demised it to some law students who wished to live quietly in the suburbs. James I. granted the Temples to certain persons from whom originated the incorporated society of the 'Students and Practicers of the Laws of England,' in whom the property is now vested. That property is extraparochial, and is separated by a wall from the rest of the city, having its own entrance gates, which are locked at night. [See INNS OF COURT.]——*Temples*, in Anatomy, the name of the sides of the face above the ears, in which are the temporal arteries, veins, &c.

TEM'PO (*Ital.*), in Music, a word used to signify time. The different degrees of time are designated by the following terms: *largo*, *adagio*, *andante*, *allegro*, and *presto*; and the intermediate degrees are described by additions. [See these terms respectively.]

TEM'PORAL (*temporalis*, pertaining to time: *Lat.*), belonging to secular concerns; not spiritual; as, the *temporal* revenues of the church, called temporalities. *Temporal courts* are those which take cognizance of civil suits.

TEM'PORAL BONES (*temporalis*, pertaining to the temples: *Lat.*), two irregular bones, one on each side of the head. Comparative anatomy shows them to be, in reality, an assemblage of five bones, the *squamous*, *zygomatic*, *tympanic*, *petrous*, and *mastoid*: continuing permanently separate in the cold-blooded classes of animals; but coalescing in the warm-blooded, with the exception of the tympanic, which remains detached in birds.

TENA'CITY (*tenacitas*: from *tenax*, holding fast: *Lat.*), the degree of force with which the particles of bodies cohere, or are held together; a term applied particularly to metals, which may be drawn into wire, as gold and silver.

TENAC'ULUM (*Lat.*), a surgical instrument, formed with a hook at one end, for taking up and drawing out the mouths of bleeding arteries, to secure them by ligaments.

TENAIL' (*Fr.*), in Fortification, an outwork consisting of two parallel sides with a front, in which is a re-entering angle. It is single or double.

TEN'AILLONS, in Fortification, works constructed on each side of the ravelins, like the lunettes; but differing in this, that one of the faces of the tenaillon is in the direction of the ravelin, whereas that of the lunette is perpendicular to it.

TEN'ANT (*Fr.*; from *tenens*, holding: *Lat.*), in Law, one who occupies lands or tenements at a yearly rent, for life, years, or at will.——*Tenant in capite*, is one who held immediately of the king. According to the feudal system, all lands in England are considered as held immediately or mediately of the king, who is styled lord paramount. Such tenants, however, were considered as having the fee of the lands and permanent possession. This tenure has been abolished: those tenures now created by the crown being in *common socage*.

TENCH, the *Tinca vulgaris* of ichthyologists, a fish of the carp family, common in ponds and rivers. It is very tenacious of life. The colour of its body is a greenish olive gold.

TEN'DER (*attendre*, to wait for: *Fr.*), a small vessel employed to attend a larger one for supplying her with provisions or naval stores, or to convey intelligence, &c.——In Law, an offer either of money to pay a debt, or of service to be performed, in order to save a liability or forfeiture which would be incurred by non-payment or non-performance. A money tender must be absolute and unconditional, in money actually produced, not in copper if it can be paid in silver, nor in silver if it can be paid in Bank of England notes or gold.

TEN'DO ACHIL'LIS (the tendon of Achilles: *Lat.*), in Anatomy, the tendon which connects the calf of the leg with the heel. It was so called, because, according to mythological fable, Thetis, the mother of Achilles, held him by that part when she dipped him in the river Styx, to make him invulnerable.

TEN'DONS, in Anatomy, white elastic fibres, which connect the muscles with the bones.

TEN'DRIL (*tendron: Fr.*), a slender twining branch, by which one plant attaches itself to another object. Sometimes it is a metamorphosed leaf which has no lamina, or which has the midrib projecting beyond it, retaining its tapering figure, and becoming long and twisted. In the vine, it is an abortive bunch of flowers proceeding from the stem opposite a leaf; in the passion flower, a metamorphosed branch, growing from the axil of a leaf; in the genus *Strophanthus*, the thin extended point of a petal. In some plants the stalk of a normal leaf has the power of twisting round an object.

TEN'ET (*tenet*, he holds: *Lat.*), an opinion, principle, or doctrine which a person believes and maintains; as the tenets of Christianity, &c.

TEN'NANTITE, in Mineralogy, arsenical sulphuret of copper and iron; a mineral of a lead colour, or iron-black, massive or crystallized, found in Cornwall.

TEN'NE (*tanné: Fr.*) in Heraldry, a colour consisting of red and yellow in the coats of gentry; which is represented in engraving by diagonal lines from the dexter to the sinister side of the shield, traversed by perpendicular lines.

TEN'NIS, a kind of play or game in which a ball is kept in motion between opposite parties who strike it with rackets.

TEN'ON (*Fr.*), in Carpentry, the end of a piece of timber, which is fitted to a mortise for insertion, &c. The form of a tenon is various, as square, dove-tailed, &c.

TEN'OR, in Music, the middle part of a composition; being the ordinary compass of the human voice, when neither raised to a treble or lowered to a bass. It is the second of the four parts, reckoning from the bass; and was originally the air, to which the other parts were auxiliary. What is called *counter-tenor* (between the treble and the tenor) is in reality only a higher tenor.

TENSE (*tempus*, time: *Lat.*), in Grammar, an inflection of verbs by which they are made to signify or distinguish the time of actions or events; as the *present tense*, denoting the time that now is; the *preterite* or *past*, the time that was; and the *future*, the time that will be. Some tenses likewise denote the state of the action, as to its completeness or otherwise, in a certain degree or time, as the *imperfect tense*, which denotes an unfinished action at a certain time; the *perfect*, a finished action at any time; and the *pluperfect*, a finished action before a certain time.

TEN'SION (*tensio: Lat.*), the state of being stretched or strained. Thus, animals sustain and move themselves by the tension of their muscles and nerves; and a chord or musical string gives an acuter or deeper sound, as it is in a greater or less degree of tension, that is, more or less stretched.——*Tension* with reference to vapours signifies elasticity. It increases with the temperature, and is usually expressed in terms of the pressure of the atmosphere or with reference to the height of a column of mercury which the given vapour is capable of supporting.——In Electrical science *tension* has reference to the quantity of electricity that any given surface may be charged with; the greater the quantity the greater the tension.

TENSONS (*contentio*, a contest: *Lat.*), Provençal poems in dialogue between two speakers, in which each recited in turn a stanza with the same rhymes. If the interlocutors were more than two it was called a *Torneyamen*. These skirmishes took place at the festivals of the barons, before a court of love composed of ladies, who discussed not only the claims of the two poets but the merit of the question, and then gravely delivered judgment. Specimens of these poems have been preserved.

TEN'SOR (*tendo*, I stretch out: *Lat.*), in Anatomy, an epithet for a muscle which extends the part to which it is fixed; as, the *tensor palati*, *tensor tympani*, &c.

TENT (*tente: Fr.*), in Surgery, a roll of lint for dilating openings, sinuses, &c.——A portable dwelling or pavilion made of canvas, used for sheltering persons from the weather, particularly soldiers in camp. The wandering Arabs and Tartars dwell in tents.

TEN'TACLE (*tento*, I try: *Lat.*), in Natural history, a filiform elongated, inarticulate appendage, placed on the head or near the mouth of many of the lower animals. They are used as instruments of exploration or prehension. Thus, the dorsal tentacles of some molluscs, the oral tentacles of Polypes, &c.

TEN'TER-GROUND (*tentus*, stretched out: *Lat.*), a place where cloth is stretched and bleached.

TENTHRE'DO, in Entomology, a genus of Hymenopterous insects, termed in English the *Sawfly*, because the female uses her sting like a saw, to cut out spaces in the bark of trees, for the purpose of depositing her eggs.

TENTORIUM, (a tent: *Lat.*), in Anatomy a covering of *dura mater* stretched over the cerebellum. It forms a bony roof in leaping animals.

TEN'URE (*Fr.* from *teneo*, I hold: *Lat.*), in Law, the manner of holding lands, &c. of a superior. [See FEUDAL SYSTEM, FEE, &c.]——*Tenures in capite*, or chief, were those held immediately of the crown; *mesne tenure*, those held of inferior lords. Under the feudal service, tenures were reduced to four kinds, *knight service* or chivalry, *free socage*, *pure villeinage*, and *villein socage*.

TERATOL'OGY (*teras*, a monster; and *logos*, a discourse: *Gr.*), that branch of phy siological science which treats of malformations and monstrosities.

TEREBIN'THINE (*terebinthinos*, made of turpentine: *Gr.*), in Chemistry, consisting of turpentine, or partaking of its qualities.

TEREBRAN'TIA (*terebro*, I bore: *Lat.*), that section of Hymenopterous insects which possesses an anal instrument for the perforation of the bodies of animals, or the substance of plants. The *borer* is peculiar to the female, and consists of one portion sheathed by two others. It is intended to prepare a suitable place for depositing the eggs, and hence is termed the ovipositor.

TEREBRAT'ULA (same *deriv.*), a genus of shell-bearing molluscs belonging to the class of *Brachiopoda*. One of the valves is perforated. Their forms (says Mr. S. P. Woodward) are symmetrical, and so commonly resemble antique lamps that they were called 'lamp-shells' by the old naturalists; the hole which in a lamp admits the wick serves in the lamp-shell for the passage of the pedicle by which it is attached to submarine objects.

TERE'DO (*Lat.*; from *tero*, I pierce), the *shipworm*, a genus of testaceous molluscs which bore their dwellings in submerged timbers, and are most destructive to sunken piles, ships' bottoms; and some small crustaceans belonging to the genera *Limnoria* and *Chelura* also bore into submerged timber and reduce it to a state resembling honeycomb.

TERM (*terminus*, a boundary: *Lat.*), in Law, the space of time formerly allotted in the courts for the trial of causes, the rest of the year being considered vacation. Business, however, has increased so much that although the terms are still kept on foot as affording dates, the judges hold sittings after the terms. In England, there are four terms in the year: Hilary, Easter, Trinity, and Michaelmas terms. Hilary term begins the 11th, and ends the 31st of January; Easter term begins the 15th of April, and ends the 8th of May; Trinity term begins the 22nd of May, and ends the 12th of June; and Michaelmas term begins the 2nd of November, and ends the 25th of November. These are subject to slight change, on account of the occurrence of certain holidays. They are observed by the courts of queen's bench, the common pleas, and exchequer, but not by the parliament or by inferior courts.——In the Arts, a word or expression that denotes something peculiar to an art: as, a technical *term*.——In Contracts, *terms* mean conditions upon which work is agreed to be performed.——In Logic, the expression, in language, of an idea obtained by the act of apprehension. It may consist of one word, or of more than one; but every word is not *Categorematic*, that is, capable of being used as a term; some, such as adverbs, prepositions, &c., are *syncategorematic*, that is, can form only part of a term. The infinitive mood is itself a term; any other part of a verb is a mixed word, resolvable into a term, and a *copula* (or auxiliary verb), which gives tense, mood, and position. Categorematics are divided into *singular*, as Cæsar'; and *common*, as 'man,' 'animal,' &c. The subject of a proposition may be either singular or common; the predicate *must* be common. When words are used in a vague or general sense, they are said to be *of the first intention;* when in the limited or specific sense, which they bear in some art or science, *of the second intention.*——*Term*, in Universities, &c., the fixed period or time during which students are compelled to reside there previously to their taking a degree. These fall within the four quarters of the year, and are distinguished by the same names as the law terms.

TERM'INAL (*terminalis*, terminal: *Lat.*), in Botany, growing at the end of a branch or stem; as, a *terminal* scape, flower, or spike.

TER'MINI (*terminus*, a boundary: *Lat.*), in ancient Architecture, figures used by the Romans for the support of entablatures, in the place of columns. The upper part consisted of the head and breast of a human body, and the lower of the inverted frustum of a cone. They were so called because they were principally used as boundary marks; and represented their god Terminus, whose altar was on the Tarpeian rock; where he was represented with a human head, without feet or arms, to intimate that he never moved, wherever he might be placed. An annual feast, called Terminalia, was held by the Romans on the 23rd of February in honour of the god Terminus. The two owners of adjacent property crowned the statue with garlands; and raised a rude altar, on which they offered some corn, honeycombs, and wine; and sacrificed a lamb, or a sucking pig. They concluded with singing the praises of the god.——Also pedestals increasing in magnitude as they rise; or parallelopipeds used for the reception of busts.

TERMIN'THUS (*terminthos*, a swelling like the fruit of the terebinth tree: *Gr.*), in Surgery, a black pustule, generally appearing on the legs. It is not certain that we mean by this term the same disease as that described by Greek writers.

TERMI'TES (the plural form of *Termes*: *Lat.*), social insects often called white ants, although of a widely different structure from true ants. There are many species, some of which inhabit our island, but the family receives its greatest development in hot countries, where some of the species build large conical houses, or *termitaria*, composed of particles of earth cemented together by their secretions into a material as hard as stone. These houses are penetrated within by galleries running in all directions from chamber to chamber. In each community besides winged males and females there are wingless neuters of two classes, fighters and workers, and both are blind. On emerging from the egg, termites have the form which they retain through life, never being grubs, and not becoming pupal like the true ants in the course of their development. In each termitarium there is a king and queen who are closely guarded by some of the workers in a chamber which lies on the middle of the house. Both are without wings, and are much larger than their subjects. As fast as the queen deposits her eggs they are carried off by the workers and placed in cells elsewhere. The ordinary males and females never work, and when they have acquired their wings they fly forth and disseminate their kind. Some of them, after shedding their wings, become kings and queens of other colonies. Some species construct nests of earth on the trunks and branches of trees; others live inside trees. Termites perform the duty of hastening the decomposition of decaying wood and vegetation.

TERMINOL'OGY (*terminus*, a term : *Lat.*; and *logos*, a discourse : *Gr.*), that branch of a science or art which explains the meaning of its technical terms. In some sciences it is of particular importance.

TER'NATE (*terni*, three each : *Lat.*), in Botany, an epithet for a leaf that has three leaflets on a petiole, as in trefoil, strawberry, bramble, &c. There are leaves also *biternate* and *triternate*, having three ternate or three biternate leaflets.

TER'RACE (*Fr.*; from *terra*, earth : *Lat.*), a platform or bank of earth raised and breasted, particularly in fortifications. Also, a raised walk in a garden, having sloping sides laid with turf.

TER'RA COT'TA (*terra cocta*, baked clay : *Lat.*), the name given to works of art formed of baked clay. Ancient specimens of terra cotta work of admirable design have been discovered in Tuscany and Rome. They consist of lamps and vessels of various kinds, besides entire figures and reliefs.

TER'RA DI SIEN'A (Siena earth : *Ital.*), a brown ferruginous ochre, employed in painting.

TER'RÆ FIL'IUS (a son of the earth : *Lat.*), a classical term for a person of low origin. Also, by an ancient custom, which was abolished about a century since, a title assumed by the undergraduate who delivered an annual oration, in which great licence was permitted.

TER'RA FIR'MA (*Lat.*), the main land; the name particularly given to a country of South America, extending from the Atlantic to the Pacific ocean, to the extent of 1,300 miles.

TER'RA INCOG'NITA (unknown land : *Lat.*), a frequent inscription on old maps.

TER'RA JAPON'ICA (Japan earth : *Lat.*), the old pharmaceutical name for *catechu*, the inspissated juice of a species of *Acacia*. It was formerly supposed to be an earthy mineral.

TERRE PLEIN (an open space : *Fr.*), in Fortification, the horizontal surface of the rampart where the guns are placed and worked. It is bounded outside by the parapet, and inside by the inner slope of the rampart.

TERRE-VERTE (green earth : *Fr.*), a species of chlorite of a green or olive colour. It is a hydrated silicate of the oxide of iron and potash with a little magnesia and alumina. The green earth of Verona, formerly used as a pigment, is a subspecies of this mineral.

TER'TIAN (*tertiana*; from *tertianus*, belonging to the third : *Lat.*), in Medicine, an ague or intermitting fever, the paroxysms of which return every alternate day.

TER'TIARY FORMATIONS (*tertiarius*, belonging to the third part : *Lat.*), in Geology, a series of strata posterior in date to the secondary (the latest portion of which is the cretaceous series), and extending to certain deposits that are termed post-pliocene. This series has been divided into groups according to the relative numbers of recent and extinct species of shells which they contain. The oldest group of beds, containing only about 3½ per cent. of recent species, has been denominated EOCENE; that with from 17 to 30 per cent. of recent shells constitutes the MIOCENE group; whilst that containing from 35 to 95 per cent. of recent shells has been formed into the PLIOCENE group.

TERZ'A RIMA (*Ital.*), the verse in which Dante composed his DIVINA COMMEDIA. In a set of six lines three rhyming lines alternate with two rhyming lines, and a third which has two corresponding rhymes in the next set of six. By this contrivance each line has always two other lines rhyming with it, except at the beginning and the end of the cantos. Thus,

ABABCB, CDCDED,

and so forth. The rhyming words in Italian poetry are all trochees.

TES'SELATED (*tesselatus*; from *tessella*, a little cube : *Lat.*), formed in little squares or mosaic work, as a *tesselated* pavement.

TES'SULAR (*tessella*, a small cube : *Lat.*), a term applied to a system of crystals, including the *cube*, *tetrahedron*, &c.

TEST (*Fr.*; from *testis*, one who attests : *Lat.*), in Chemistry, a term applied to any substance which serves to detect the presence of any constituent in a compound; thus barytes will indicate the presence of sulphuric acid; starch that of iodine, &c. Also, in Metallurgy, a cupel or pot for separating base metals from gold or silver.

TESTA'CEA (*Lat.*; from *testa*, a shell), in Natural History, a name given to such of the class mollusca as have shells. [See MOLLUSCA, SHELLS.]

TES'TAMENT (*testamentum*; from *testor*, I make a will : *Lat.*), in Law, a solemn authentic instrument in writing, by which a person declares his last will, as to the disposal of his estate and effects after his death. [See WILL.]——*Testament*, in Theology, the name of each of the volumes of the Holy Scriptures, that is, of the Old and the New Testament. The first *Testament* printed in the English language appeared in 1526. This translation was made by William Tyndale, and was published abroad, after which it was circulated at Oxford and London. Tonstall, bishop of London, and Sir Thomas More, bought up almost the whole impression, and burnt it at St. Paul's Cross.

TEST AND COR'PORATION ACTS, the usual designation for statutes, by which all magistrates in corporations, and all who bear any office civil or military, are to take the oaths of allegiance and supremacy, to renounce the doctrine that it is lawful to bear arms against the sovereign; and within a year before their election, receive the sacrament, according to the rites of the Church of England. There were intended to be the bulwarks of the Protestant church, but have been long evaded by means of acts of indemnity passed annually for the relief of those neglecting to comply with them, and in many cases the necessity for taking these tests has been abolished.

TESTIMONY (*testimonium;* from testis, *a witness: Lat.*), the evidence of facts, oral, as in a court of law; or written, as in the records of history. Testimony is probable and credible when in accordance with general experience, corroborated, and disinterested; but improbable, and unworthy of credit, when contrary to general experience, and uncorroborated.

TEST'ING (*teste,* the cupel used by refiners: *Fr.;* from *testa,* baked earthenware: *Lat.*), in Metallurgy, the operation of refining large quantities of gold or silver by means of lead, in the vessel called a *test.* In this process the extraneous matter is vitrified, scorified, or driven off, and the metal left pure.

TESTU'DO (a tortoise: *Lat.*), in Zoology, a genus of tortoises. [See TORTOISE.]——*Testudo,* in the Military art of the ancients, a contrivance used by the Greeks and Romans in attacking fortified places. It was formed by the troops holding their shields over their heads, so as that one overlapped another, and formed a penthouse, which threw off the missiles of the enemy from the soldiers, as they approached the walls. It received its name from its resemblance to the shell of a tortoise. A similar defence was sometimes formed of boards, and moved on wheels.

TET'ANUS (*Lat.;* from *tetanos,* literally a stretching: *Gr.*), in Medicine, a spasmodic contraction of the muscles of voluntary motion, particularly of those which shut the lower jaw; this is termed a *locked jaw.* It is frequently caused by lacerated wounds, which are not necessarily of a severe character; also, in hot climates, by exposure to cold, and suppressed perspiration; in the former case it is generally fatal, in the latter is sometimes cured.

TET'RACHORD (*tetra,* four; and *chordē,* a string; *Gr.*), in Ancient Music, a concord consisting of four degrees or intervals, and four terms or sounds; called by us a fourth.

TET'RAD (*tetras,* the number four: *Gr.*), the number four; a collection of four things.

TETRADAC'TYLOUS (*tetra,* four; and *daktulos,* a finger: *Gr.*), having four toes.

TETRADIAPA'SON (*tetra,* four; and *diapason,* the octave: *Gr.*), a musical chord, otherwise called a quadruple eighth or twenty-ninth.

TETRADRACH'MA (*tetradrachmos: Gr.*), in ancient coinage, a silver coin worth four drachmas, or 2*s.* 7*d.*, the drachma being estimated at 7¾*d.* sterling.

TETRADYNA'MIA, the 15th class of the Linnæan system of plants; containing two orders, *siliculosa* and *siliquosa,* with four long and two short stamens.

TET'RAGON (*tetra,* four; and *gōnia,* an angle: *Gr.*), in Geometry, a figure having four angles, as a square, a rhombus, &c.

TETRAGYN'IA, in Botany, one of the orders in several of the Linnæan classes, comprehending those plants which have four pistils.

TETRAHE'DRAL (*tetra,* four; and *hedra,* a base: *Gr.*), having four equal sides.——In Botany, having four sides; as a tetrahedral pod or silique.

TETRAHE'DRON (same *deriv.*), in Geometry, a figure comprehended under four equilateral and equal triangles. It is one of the five *Platonic bodies,* or regular solids.

TETRAHEXAHE'DRAL (*tetra,* four; *hex,* six; and *hedra,* a base: *Gr.*), in Crystallography, exhibiting four ranges of faces, one above another, each range containing six faces.

TETRAN'DRIA (*tetra,* four; and *anēr,* a male: *Gr.*), the fourth class of the Linnæan system of plants, comprising plants bearing flowers, with four stamens.

TETRA'O (a black cock, or black grouse: *Lat.*), in Ornithology, a genus of rasorial birds, including the grouse, capercailzie, and ptarmigan.

TETRAPET'ALOUS (*tetra,* four; and *petalon,* a leaf: *Gr.*), in Botany, containing four distinct petals or flower leaves.

TETRAPH'YLLOUS (*tetra,* four; and *phullon,* a leaf: *Gr.*), in Botany, consisting of four distinct leaves or leaflets; as a *tetraphyllous* calyx.

TETRAP'LA (*tetraplous,* fourfold: *Gr.*), in Ecclesiastical History, a bible arranged by Origen in four columns, each containing a different Greek version: one being the Septuagint; and the others those of Aquila, Symmachus, and Theodosius.

TE'TRARCH (*tetrarchēs;* from *tetra,* four; and *archo,* I govern: *Gr.*), a Roman governor of the fourth part of a province. Such originally was the import of the title tetrarch; but it was afterwards applied to any petty king or sovereign. The office, or the territory of a tetrarch was called a *tetrarchate.*

TETRASPER'MOUS (*tetra,* four; and *sperma,* seed: *Gr.*), in Botany, an epithet for a plant which produces four seeds in each flower; as the rough leaved or verticillate plants.

TETRAS'TICH (*tetrastichos;* from *tetra,* four; and *stichos,* a line: *Gr.*), a stanza, epigram, or poem consisting of four verses.

TETRAS'TYLE (*tetrastulos;* from *tetra,* four; and *stulos,* a column: *Gr.*), in Ancient Architecture, a building with four columns in front.

TET'TER (*teter: Sax.*), in Medicine, a common name of several cutaneous diseases. Also, a disease of animals, of the ring-worm kind.

TEUTON'IC, belonging to the Teutones, an ancient people of Germany. The Teutonic language is the parent of the German, Dutch, and Anglo-Saxon.——*Teutonic order,* a religious order of knights, established towards the close of the twelfth century, and thus called as consisting chiefly of Germans or Teutones. The original object of the association was to defend the Christian religion against the infidels, and to take care of the sick in the Holy Land. It was at one period immensely rich and powerful, and it still retains a titular existence in Austria.

TEXT (*texte: Fr.*; from *textus: Lat.*), a term signifying an original discourse, exclusive of any note or commentary. Also, a certain passage of scripture, chosen by a preacher to be the subject of his sermon. ——*Text-book* a book containing the leading principles or most important points of a science or branch of learning, arranged in order for the use of students.

TEX'TILE (*textilis: Lat.*), an epithet given to whatever is woven or capable of being woven. *Textile fabrics* accordingly signify stuffs of every description, no matter what the materials may be of which they are composed.

THALAM'IFLORÆ (*thalamus*, a receptacle; *flos*, a flower: *Lat.*), in Botany, a subclass of flowering plants, comprehending those which have distinct petals and stamens which proceed from beneath the ovary. Such plants have both a calyx and corolla, and the petals are inserted into the receptacle. The ranunculus and poppy orders may be taken as examples.

THAL'LOGENS (*thallos*, a frond; *gennao*, I produce: *Gr.*), in Botany, a vast class of cryptogamic plants of low organization. They are destitute of true stems, and of a vascular system, consisting simply of expansions of cellular tissue. Sea weeds, funguses, and lichens belong to this class.

THAL'LIUM, one of the metals recently discovered by means of spectrum analysis. It has been found in certain mineral waters, but the largest quantity has been yielded by flue-dust. It has a metallic lustre, with a colour near that of tin. Its specific gravity is 11·9. It is very soft, being easily scratched by lead, is very malleable, but is with difficulty drawn into wire. Rubbed on paper it gives a dark mark, which rapidly fades. Its melting point is 550° F., and it vaporises at a little higher temperature. It yields, during combustion in the flame of a spirit-lamp, an intense green colour (whence its name, from *thallos*, *Gr.*, a green bud); and it communicates a single green line to the spectrum, by which line it was originally detected.

THAM'MUZ, the tenth month of the Jewish civil year, containing 29 days, and answering to a part of June and of July. ——In Mythology, the name under which the Phœnicians worshipped Osiris, or Adonis.

THANE (*thegn: Sax.*), a title of honour among the Anglo-Saxons. Its original meaning was servant, and it was applied to the followers of kings and chieftains; but it was afterwards given to all landed proprietors above the degree of alderman, and under that of earl. There were superior and subordinate thanes.

THAU'MATROPE (*thauma*, a wonder; and *trepo*, I turn: *Gr.*), an optical device to exhibit the *persistence of vision*. The principle is well exemplified by rapidly whirling round a burning stick, which apparently produces a circle of fire. [See PHENAKISTOSCOPE.]

THE'A (*tcha: Chin.*), in Botany, the systematic name of the tea tree. [See TEA.]

THE'ATRE (*theatron*; from *theaomai*, I behold: *Gr.*), a building for the exhibition of dramatic performances. The most ancient theatres in Greece and Rome were temporary, being composed of boards placed gradually above each other for the convenience of spectators. The improvements of the theatre kept pace with dramatic taste; and they were eventually built in a handsome and durable manner, rivalling in size and splendour the most costly edifices. The first royal licence for a theatre in England was granted in 1557, to James Burbage and four others, servants to the Earl of Leicester, to act plays at the Globe, Bankside, or in any part of England; but long before their time *miracles* were represented in the open fields. Dramatic exhibitions of all kinds were opposed by the Puritans in 1633, and suspended till 1660, when Charles II. licensed two companies, Killegrew's and Davenant's; the first at the Bull, Vere Street, Clare Market, which in a year or two was removed to Drury Lane; the other in Dorset Gardens. Till that time boys performed women's parts. Sir William Davenant introduced operas; both companies united, 1684, and continued together till 1694; when the principal of them, under Betterton, obtained a licence, and withdrew to Portugal Street, Lincoln's Inn Fields, in 1695. [See DRAMA.]

THE'ISM (*Theos*, God: *Gr.*), the belief or acknowledgment of the existence of a God, as opposed to *Atheism*. It has sometimes been defined to be *Deism*; but *Theism* differs from *Deism*, for although Deism implies a belief in the existence of a God, yet it signifies in modern usage a denial of revelation, which *Theism* does not.

THEOC'RACY (*theokratia*: from *Theos*, God; and *kratos*, power: *Gr.*), a state governed by the immediate direction of God.

THEOD'OLITE, a mathematical instrument much used in surveying, for the taking of angles. It consists of a small telescope, which may be moved both vertically and horizontally; the vertical and horizontal angles described with it, being indicated by graduated circles.

THEOG'ONY (*theogonia: Gr.*), that branch of the heathen theology which taught the genealogy of their gods.

THEOLO'GIUM (*Theos*, a god; and *logeion*, a speaking place: *Gr.*), in the ancient theatre, a kind of little stage, above that on which the ordinary actors appeared; being the place where the machinery of the gods was arranged.

THEOL'OGY (*theologia*; from *Theos*, God; and *logos*, a discourse: *Gr.*), the study of religion. It may be divided into several branches, as, 1. *Exegetical theology*, which consists in the explanation and interpretation of the scriptures. 2. *Didactic* or *speculative* theology, by which the several doctrines of religion are stated, explained, and supported. 3. *Systematic theology*, which arranges religious dogmas methodically, so as to enable us to contemplate them in their natural connection, and to perceive both the mutual dependence of the parts and the symmetry of the whole. 4. *Practical theology*, which consists of an exhibition, first, of precepts and directions; and, secondly, of the motives for complying with them.

THEOMAN'CY (*Theos*, God; and *manteia*, prophecy: *Gr.*), a species of prophecy in which a god himself was believed to reveal future events; as, when a deity spoke through an oracle, or by means of a sibyl.

THEOR'BO (*tiorba: Ital.*), a musical instrument made in form of a large lute, except that it has two necks. It was formerly used by the Italians for playing a thorough bass.

THE'OREM (*theōrēma*; from *theoreo*, I look at: *Gr.*), in Geometry, a something proposed to be *proved*; in contradistinction to a *problem*, which requires something to be *done*. A theorem requires a *demonstration*; a problem, a *solution*.——In Algebra or Analysis, it is sometimes used to denote a rule, particularly when that rule is expressed by symbols. A *universal theorem* extends to any quantity without restriction. A *particular theorem* extends only to a particular quantity, as a *negative theorem* expresses the impossibility of any assertion.

THE'ORY (*theōria*, a looking at: *Gr*). All men in every rational action of their lives are followers of theory, and they may be divided into those who follow good, and those who follow bad, theory. It is therefore a matter of importance to discover the difference between good and bad theory, to ascertain the tests by which one may be distinguished from the other. The real object is to discover cases of constant sequences, and when such a case of constancy has been found and correctly set forth in words, we have arrived at a correct theory. But when the proposition which professes to express a case of constant sequence gives us, in point of fact, a case which is not constant, we have before us a wrong theory. Of correct theories, however, some relate to things which have but little relation to the concerns of man, whilst others are founded on facts that have a close connection with the happiness of our race. It is the latter class of theories that are of importance to us; and the degree of that importance must always be in proportion as the sequences which they formulise have an influential bearing on man's life. Moreover, whilst one theory, though correct as far as it goes, expresses but a short sequence of events, another will embrace a much larger sequence, and summarise a much greater number of facts. The latter kind of theory is, of course, the most valuable, since more knowledge is of greater worth than less. It may be laid down as incontrovertible that the man whose mind is furnished with a greater number of correct theories is better off with regard to correct practice, other things being equal, than the man who possesses fewer correct theories. If theory were proscribed, if men were unable or unwilling to collect the result of their observations into general formulæ, civilisation would cease to exist, and there could be no advance beyond the stage of mere animality.——An exposition of the principles of any science, as the *theory* of music.——The philosophical explanation of phenomena, either physical or moral, as Newton's *theory* of optics; Smith's *theory* of moral sentiments.

THEOS'OPHIST (*Theos*, God; and *sophistēs*, a wise man: *Gr.*), one who pretends to derive his knowledge from divine illumination.

THERAPEU'TÆ (*therapeutes*; from *therapeuo*, I attend upon: *Gr.*), a term applied to those who are wholly employed in the services of religion; but specially to a particular sect of men, concerning whom there have been great disputes among the learned. It is generally supposed that St. Mark established a particular society of Christians about Alexandria, of whom Philo gives an account, and calls them *Therapeutæ*. He speaks of them as a sect, retired from the world, who spent their time in reading the writings of ancient authors, in singing hymns and songs composed by some of their own sect, and in dancing together the whole night. Some suppose they were *Essenes*; others imagine they were Jews, residing in Egypt; Eusebius and others consider them as Christians.

THERAPEU'TICS (*therapeutikos*, sanative: *Gr.*), that part of medicine which relates to the modes of action and effects of remedies, and their application for the prevention and cure of diseases.

THERI'ACA (*Gr.*: literally, belonging to wild beasts), a name given by the ancients to various compositions esteemed efficacious against the effects of poison. Some few have been transferred to comparatively modern pharmacopœiæ under the names of the *theriaca of Andromachus*, the *theriaca Veneta*, the *confectio Mithridati*, &c. They were in the form of confections, and extremely complicated. The theriaca Veneta was a compound of sixty-four drugs, prepared, pulverized, and reduced by means of honey to an electuary.

THERMAL WATERS (*thermē*, heat: *Gr.*), warm or tepid mineral waters, whose heat varies from 92° to 112°.

THERMO-ELECTRICITY, the electricity developed by *change of temperature*. It is most probably that electricity which, being developed by the successive heating and cooling of the earth's surface during rotation on its axis, causes the earth to be a magnet. If two pieces of copper wire are attached to a delicate galvanometer, on bringing the free ends together, between the finger and thumb, sufficient electricity will be set free to deflect the needle. The most convenient apparatus for exhibiting thermo-electrical currents consists of alternate bars of antimony and bismuth soldered together at their ends, so as to form a compound bar. If this is placed with one set of its soldered joints resting on ice, and a bar of hot iron resting on the other set, a current of electricity will be perceived when the outer bars are connected with the galvanometer Thermo-electricity has been termed *stero-electricity* (*stereos*, solid: *Gr.*), on account of being produced by solids without the use of a fluid.

THERMOM'ETER (*thermē*, heat; and *metron*, a measure: *Gr.*), an instrument for measuring the degree of sensible heat. The ordinary thermometer consists of a slender glass tube, having a bulb at one end, and being hermetically sealed at the other. The bulb and a portion of the tube contain mercury, or alcohol coloured—almost always the former; the rest of the tube is a vacuum. When the temperature is raised or lowered, the fluid expands or contracts, so as to occupy a portion of the tube less or greater than before; and the amount of expansion or contraction is indicated by a scale attached to the instrument. There are two fixed points in a thermometer, from which the graduation is made: one, the freezing point of water, which is unchangeable; the other, the boiling point of the same fluid, which also, *with a given atmospheric pressure*, is unvariable. The *zero*, or 0, of *Fahrenheit* is 32° below the freezing point; it is the temperature obtained by a mixture of snow and salt, which he erroneously supposed was the lowest possible; the boiling point of water is 212°. The thermometer of Fahrenheit is chiefly used in this country. In the *Centigrade* thermometer, the zero is the freezing point; and 100° the boiling point of water. This thermometer has been adopted in France, and very generally in science. In the thermometer of *Reaumur*, the zero is also the freezing point; but 80° is the boiling point of water. This thermometer is used in Germany. Thermometers have been so constructed as to register of themselves the highest and lowest degrees of temperature to which they have been brought, within a certain period; and are termed *self-registering maximum and minimum thermometers*. It is not certainly known by whom the thermometer was invented; it dates from about the beginning of the 17th century; the Dutch ascribe it to Cornelius Drebbel, the Italians to Sanctorio.

THER'MOSTAT (*thermē*, heat; *statos*, a standing: *Gr.*), the name of an apparatus for regulating temperature in distillation, ventilating apartments, heating baths or hothouses, &c. That invented by Ure acts on the physical principle, that when two thin metallic bars of different expansibilities are rivetted or soldered facewise together, any change of temperature in them will cause a sensible movement of flexure in the compound bar, to one side or other; which movement may be made to operate, by the intervention of levers, &c., in any desired degree upon valves, stopcocks, stove-registers, air-ventilators, &c.: so as to regulate the temperature of the media in which the compound bars are placed.

THE'SIS (*Gr.*, literally, a placing), a position or proposition which a person advances, and offers to maintain; or which is actually maintained by argument. The term is more particularly applied to the questions propounded, in most of the Scotch and continental universities, to the students, previously to their obtaining a degree.

THIRST, the desire for drink, arising from a dryness and heat of the mouth, sometimes extending along the œsophagus to the stomach. During thirst, the posterior fauces become red, the mucous secretion and saliva thick, and viscid; a vague inquietude, restlessness of mind, and quick pulse follow; and unless drink is obtained, respiration becomes laborious, and the mouth opens to admit the cool air. Habitual thirst is produced by excess in drinking. After exercise in warm weather, milk and water, or warm tea, is far better than beer, wine, spirits, &c., which, in such cases, generally produce febrile action.

THIRTY YEARS' WAR, the war carried on between the Roman Catholics and Protestants, in the first half of the 17th century. It is considered to have begun with the insurrection of the Bohemians, in 1618; and to have ended with the peace of Westphalia, in 1648.

THIS'TLE, the common name of rough prickly plants belonging to the sub-order *Cynarocephalæ* of the nat. ord. *Compositæ*, especially the species of the genus *Carduus*. The stem is thick and herbaceous; the leaves more or less pinnated, and beset with spines; the flowers are disposed in large dense heads, surrounded with a close, scaly, and usually spiny involucre.

THO'MISTS, the followers of Thomas Aquinas, with respect to predestination and grace; in opposition to Scotus.

THOM'SONITE, a mineral of the *Zeolite* family, occurring generally in masses of a radiated structure.

THOR, a Scandinavian deity, the son of Odin and Freya, who presided over mischievous spirits inhabiting the air. He appears to have been in some respects confounded with Jupiter; and hence the day sacred to that god was dedicated to Thor, under a name retained in English, in the word *Thurs-day*.

THORAC'IC (*thōrax*, the breast: *Gr.*), in Ichthyology, a term applied to the ventral fins of fishes when they are placed in front of the pectoral fins.——*Thoracic duct*, in Anatomy, the trunk of the absorbent vessels, which is of a serpentine form.

THO'RAX (*Gr.*), in Anatomy, that part of the human skeleton which consists of the bones of the chest; also, the cavity of the chest.

THORI'NA, in Mineralogy, a primitive earth found in thorite, a Norwegian mineral, the hydrated oxide of thorina, which is the oxide of thorium. Thorina is white, infusible, and very heavy, its spec. grav. being 9·4; no acid dissolves it except sulphuric acid, and that with difficulty. It is known from alumina and glucina by being insoluble in potash; and from zirconia by being precipitated with ferrocyanide of potassium.

THOROUGH-BASS, in Music, the art of composition according to the rules of harmony. This branch of the musical science is twofold, *theoretical* and *practical*. Theo-

retical thorough-bass comprehends the knowledge of the connection and disposition of all the several chords, harmonious and dissonant; and includes all the established laws by which they are formed and regulated. *Practical* thorough-bass supposes a familiar acquaintance with the figures, a facility in taking the chords they indicate, and judgment in the various applications and effects of those chords in accompaniment.

THRUSH, the common name of some birds belonging to the genus *Turdus*, in the family *Merulidæ*. In Britain there are three species, the Missel Thrush (*T. viscivorus*), White's Thrush (*T. Whitii*), and the Song Thrush or Throstle (*T. musicus*). The last is one of the finest singing birds in this country. Its song, which is rich and varied, commences early in the season, and continues for nine months. It is not migratory, but is supposed in winter to remove from the more northern to the southern provinces of England.——*Thrush*, in Medicine, ulcers in the mouth and fauces

THUGS (*thuggee*, a deceiver: *Hind.*), an association of murderers formed of men of all castes, and from all parts of India. 'Their origin is uncertain, but it is supposed to date from soon after the Mohammedan conquest. They now claim a divine original, and are supposed to have supernatural powers, and to be the emissaries of the divinity, like the wolf, the tiger, and the bear. Many belong to the most amiable, intelligent, and respectable classes of the lower and even middle ranks; they love their profession, regard murder as sport, and are never haunted with dreams or troubled with pangs of conscience during hours of solitude or in the last moments of life. The victim is an acceptable sacrifice to the goddess Davee, who by some classes is supposed to eat the lifeless body, and thus save her votaries the necessity of concealing it. They are extremely superstitious, always consulting omens All worship the pick-axe, which is symbolical of their profession, and an oath sworn on it binds closer than on the Koran. They rise through various grades: the lowest are scouts; the second sextons, the third are holders of the victims' hands; the highest, stranglers. All agree in never practising cruelty, or robbing previous to murder, in never allowing any but infants to escape (and these are trained to Thuggee), and in never leaving a trace of such goods as may be identified. Murder of woman is against all rules A mild-looking man who had been born and bred to the profession, had committed many murders, saw no harm in them, and felt neither shame nor remorce, explained to me how the gang waylay the unwary traveller, enter into conversation with him, and have him suddenly seized, when the superior throws his own linen girdle round the victim's neck and strangles him, pressing the knuckles against the spine. One assassin frankly confessed to having been engaged in 931 murders. Sometimes 150 persons collect into one gang, and their profits have often been immense; the murder of six persons on one occasion yielding upwards of 8000*l*. The profession have particular stations which they generally select for murder, throwing the body of their victim into a well.'—DR. J. D. HOOKER. The government has exerted itself so energetically to put down this horrible association that several thousands of Thugs have been seized, and some hundreds hanged, so that these wretches are now seldom heard of where they once swarmed.

THULE, a name given by the ancients to the most northern country with which they were acquainted. Some authors imagine it to have been Iceland; others consider it to have been the coast of Norway; while there are many who have not attached to it the idea of any precise country.

THUM'MIM, a Hebrew word, denoting perfection The Urim and Thummim were precious stones on the high priests' vestments, which were consulted by the Jews to learn the will of God as long as their government was a *Theocracy*.

THUN'DER, the report which accompanies the discharge of electric fluid in the clouds, or between them and the earth. When this explosion is near, the thunder has a rattling or clattering sound; and when distant, a heavy and rumbling. This sharpness of the sound when near, and its rumbling when distant, are the principal means by which we can ascertain its proximity or distance. There are two ways of explaining the production of thunder by the electrical discharge: one that the electricity opens for itself a passage through the air, like a projectile; and that the sound is caused by the rush of air into the vacuum which follows, the reverberation being produced by the clouds. The other, that when the electric fluid passes between two points, there is a decomposition and recomposition of the electricity in all the intervening media; and therefore a more or less violent vibration, which gives rise to sound. The continued roll would arise from the comparatively slow propagation of sound through the air. During a thunderstorm, proximity to lofty objects, and good conductors, should be carefully avoided. [See LIGHTNING] Hence it is unsafe, in such circumstances, to be near trees, sheets of water, gilt furniture, bellwires, &c. It is dangerous to be near a fireplace, on account of the quantity of metal it contains, and the likelihood of the chimney being struck. It is not safe to be in a large open plain. The middle of the house is the best place, and the security is increased by sitting on a good non-conductor: such as a feather bed, mattress, &c.

THURS'DAY. [See THOR.]

THYME (*thumos: Gr.*), in Botany, a labiate plant of the genus *Thymus*. The garden thyme is a warm, pungent aromatic, much in use for culinary purposes. Its essential oil is extremely acrid and pungent.

THY'MUS (*Lat.; from thumos: Gr.*), in Anatomy, a glandular body divided into lobes, situated behind the sternum. It is largest in the fœtus, diminishes after birth, and in adults often entirely disappears. In calves it is called the *sweetbread*.

THY'ROID (*thureos*, a shield; and *eidos*, form: *Gr.*), in Anatomy, a term applied to one of the cartilages of the larynx. The thyroid or scutiform cartilage is largest in men, in whom it is sometimes very prominent, and obtains the name of *Adam's apple.*—The *thyroid gland* is situated near the thyroid cartilage, and the *thyroid veins* and *arteries* belong to it.

THYRSE, or THYRSUS (*thursos*, the stalk of umbelliferous plants: *Gr.*), in Botany, a species of inflorescence; a dense or close panicle, with the peduncles longest at the middle, and therefore more or less of an ovate figure, as in the lilac.

THYR'SUS (*thursos: Gr.*), in Antiquity, an attribute of Bacchus and his votaries. It consisted of a wand wreathed with ivy and vine leaves, with a pine cone at the top. It was used at all the festivals held in honour of the god of wine.

THYSANOP'TERA (*thusanoi*, fringes; *pteion*, a wing: *Gr.*), in Entomology, an order of small insects formerly comprehended amongst the *Hemiptera*. They have two pairs of wings, which are narrow and fringed with long hairs. Their metamorphosis is incomplete, the larvæ resembling the perfect insects, except that they have no wings. The typical genus is *Thrips;* of which one species, the *T. cerealium*, sometimes does great damage to the grain crops. Other species attack various other plants, and inflict much injury.

TIA'RA (*Gr.*), the covering for the head used by the ancient Persians. It was in the form of a tower, adorned with peacock's feathers; was sometimes encompassed with a diadem; and often had a half-moon embroidered on it.—Also, the crown worn by the Popes. At first they used only a high round cap like the other bishops. Nicholas I. added the first gold circle, as a sign of the civil power; Boniface added the second, about the year 1300; and Urban V. the third, about 1365.

TIB'IA (*Lat.*), in Anatomy, the largest of the two bones which form the leg.—In Entomology, the fourth joint of the leg; it is very long.

TIC DOULOUREU'X (*Fr.*), in Medicine, a most painful affection of a facial nerve, deriving its name from its sudden and excruciating stroke. It is characterized by acute pain, attended with convulsive twitchings of the muscles; and is regarded as one of those diseases which generally baffle medical skill.

TICK, the popular name of certain parasitic insects, which belong to the genus *Ixodes*, in the class *Arachnida*. They have four pairs of legs, and a rostrum, which they bury in the skin of animals, whose blood they suck until their originally flat and oval bodies are distended into a globular form. They are found in woods upon brushwood, grass, &c., from which they transfer themselves to the bodies of passing animals.

TIDES, the *flux* and *reflux*, or rise and fall of the sea. The phenomena connected with the tides are not very numerous, nor, with our present knowledge, hard to be explained. The tides are a consequence of the attraction of gravitation. The earth revolves on its axis once a day, and the moon is retained in its orbit by the mutual attraction which exists between it and the earth. These two facts suffice to explain the tides. The water on the side of the earth next the moon, the water on the side of the earth farthest from the moon, and the mass of the earth between both, are all attracted by the moon with different forces, on account of their different distances. The waters next the moon are attracted most, and therefore fall most towards the moon, leaving the earth behind, and bulging out from it. The waters farthest from the moon are less attracted by the moon than the mass of earth in front of them: and therefore, being left behind by the earth, which is drawn more towards the moon, they bulge out behind. Hence there will be high water under the moon, because the water moves towards the moon faster than the earth; and also high water at the same time at the opposite side of the earth, because the mass of earth moves towards the moon faster than the water behind it. The two masses of water, or tides, are equal: since the water in one of them flows as much more rapidly towards the moon than the earth as the earth moves more rapidly towards the moon than the water in the other. The water flows from all directions to form these heaps, as they may be termed; the resulting currents are modified by promontories, islands, winds, &c., and by the fluid having a less velocity of rotation than that part of the earth to which it flows, on account of coming from the neighbourhood of the poles. As time is required for the communication of motion, the highest part of the tidal wave is not immediately under the moon, but about 30° to the eastward of it. There are two tides in twenty-four hours; one on the side of the earth *next* the moon, another on the side *farthest* from the moon. The tide is about fifty minutes later, in any given place, on each succeeding day; because that place cannot return to its former position in less than a day; and it has besides to follow the moon, which has moved on in her orbit. The sun also causes tides; but though it is larger than the moon, its effect is less, on account of its greater distance. When the sun and moon act together, that is when they are in *conjunction* or in *opposition*, the tides are larger, and are called *spring* tides, which occur a little after new and full moon, not exactly at the happening of these events, because time is required for the communication of motion. When the moon is in *quadratures* the effects of the sun and moon are opposed; and there are small, or *neap tides*. When the sun and moon, or both, are nearest to the earth, the tides produced by them are highest: hence the tides are greatest after the autumnal, and before the vernal equinox. The effects of the planets in causing tides are inappreciable. There must evidently be tides in the atmosphere; though, as we are immersed in that fluid, they are ordinarily imperceptible to us. The extreme practical importance of a correct knowledge of the tides, on coasts and in harbours, has in many places led to the prosecution of some sort of regular observations, to determine what is called the *establishment* of particular ports: that is, the interval of time after the new and full moon has passed the meridian, at which it is high water in them; from this the time of high water on other days is known by the age of the moon.

TIERCE (*tiers: Fr.*), in Heraldry, an epithet for the field when it is divided into three parts.

TIERS ETAT (the third estate: *Fr.*). This term was universally applied in France to the mass of the people under the old *régime*. Before the cities rose to wealth and influence, the nobility and clergy possessed the property of almost the whole country, and the people were subject to the most degrading humiliations. But, as trade and commerce began to render men independent, and they were able to shake off their feudal bonds, the *tiers état* gradually rose into importance; and at length the third estate, during the revolution, may be said to have become the nation itself.

TI'GER, the *Tigris regalis* of naturalists, a powerful beast of the feline family inhabiting the East Indies, and some other parts of Asia; but, wherever it is known, its strength and sanguinary disposition are such as to excite the terror of the inhabitants. It comes into the midst of villages in the night time, for the purpose of carrying off cattle, and it has often been known to single out for prey some human victim. No animal, except the elephant, is capable of resisting it. The Bengal tiger has an average length of eight feet, and is between three and four feet high. It is of a yellowish brown colour, with transverse black stripes; and the tail has alternate black and yellow rings.

TIL'LER, a lever or piece of wood fastened in the head of the rudder, by which it is moved. In small ships and boats it is called the *helm*.——*Tiller-rope*, the rope which forms a communication between the fore end of the tiller and the wheel.

TIM'BER, a name for all kinds of wood to be used in Building, Carpentry, Joinery, Turnery, &c. We also apply the word to standing trees which are suitable for these purposes. Timber is preserved from that particular kind of decay called dry rot by saturating it with solutions of various metallic salts, such as copperas (sulphate of iron), corrosive sublimate (bichloride of mercury), chloride of zinc, and sulphate of copper. Creosote has also been employed for the same purpose.——In ships, a *timber* is a rib piece of wood, branching outward from the keel in a curving direction.

TIM'BREL (*timbré*: *Fr.*; from *tympanum*, a drum: *Lat.*), an ancient musical instrument; a kind of tabor or tambourine, frequently mentioned in Scripture.

TIME, a portion of duration, whether past, present, or future; marked by certain periods or measures, chiefly by the motion and revolution of the sun.——*Absolute* time is that which is considered in itself, without reference to the portion of duration to which it belongs.——*Relative* time is that which is considered with reference to the termini of some specific interval of duration.——*Apparent* time is that deduced from observations of the sun: that which is shown by a good sun-dial.——*Mean* time is that shown by a well-regulated watch: it is not the same as that shown by a sun-dial, because the apparent motion of the sun in the heavens is not uniform.——*Sidereal* time is that portion of a sidereal day which has elapsed since the transit of the first point of Aries. It represents, at any moment, the right ascension of whatever heavenly body is then on the meridian.——*Astronomical* time of the day is reckoned from the mean noon of that day, and is reckoned on to twenty-four hours in mean time.——*Civil* time is mean time, applied to the purposes of civil life. The civil day commences at the midnight preceding the noon of the day, and it is divided into two parts of twelve hours each; the first twelve hours being A. M. or *ante meridian* (before noon); the second twelve hours being P. M. or *post meridian* (after noon).——*Time*, in music, the measure of sounds, with reference to their continuance or duration. Thus, in *common time*, the bar is equal in length to a semibreve, or a minim, according to the character used to indicate the time; in *triple time*, it is that part of a semibreve expressed by the fraction placed at the beginning of the staff—thus $\frac{3}{4}$ means three-fourths of a semibreve, or three crotchets; $\frac{12}{8}$, twelve eighths of a semibreve, or twelve quavers, &c. The time is also affected by certain technical terms employed; such as *allegro*, *presto*, &c

TIMOC'RACY (*timē*, an assessment; *kratos*, power: *Gr.*), that form of government whose laws require a certain property, or position in society, to enable a citizen to be capable of the highest offices.

TIN, a metal of a silver-white colour, very ductile and malleable. Its spec. grav. is 7·29. It gives out, while bending, a crackling noise; is fusible at about 442°, a heat much less than that of ignition; is soluble in muriatic acid, and is rapidly converted, by dilute nitric acid, into a white oxide. Tin has been known from the earliest ages. It was much employed by the Egyptians in the arts, and by the Greeks as an alloy with other metals. Pliny speaks of it under the name of *white lead*, as a metal well known in the arts, and even applied in the fabrication of many ornaments of luxury. He ascribes to the Gauls the invention of the art of tinning, or covering other metals with a thin coat of tin. The Phœnicians procured it from Spain and from Britain, with which places they carried on a very lucrative commerce. According to Aristotle, the tin mines of Cornwall were known and worked in his time; and they still continue the most productive of any in Europe. Diodorus Siculus, who wrote 40 years before Christ, describes the method of working these mines; and says that their produce was conveyed to Gaul, and thence to different parts of Italy. Tin which is very pure, but not so easily manufactured as the Cornish, is also obtained in great quantities in South America. The first process to which tin ore is subjected is grinding; it is then washed, to remove the impurities. The specific gravity is so high that it is easy to wash away the earths, and even some of the foreign metallic ores with which it is often mingled. The next process is roasting the ore in a reverberatory furnace along with anthracite, which removes the oxygen and foreign matters. It afterwards repeatedly undergoes the effects of fusion, and being at length purified from the admixture of all foreign substances, it is cast into blocks, weighing each about 300 lbs. There are only two ores of tin—the *peroxide*, which is tin-stone or capiterite, and *tin pyrites*, which is sulphuret of tin or stannine; the former, only, is sufficiently abundant for metallurgic purposes. Tin unites easily with various metals; combined with copper in different proportions, it forms *bronze, bell metal*, and other useful alloys. Lead and tin may be combined in any proportion by fusion; the resulting alloy is harder, and possesses much more tenacity than tin; and these qualities are at a maximum when it is composed of three parts of tin and one of lead. Alloyed with small proportions of antimony, copper, and bismuth, tin is formed into various wares resembling silver, under the names of block-tin, Britannia metal, &c. Tin is much used in the state of very thin leaves; it is then called *tin-foil*. This is made from the finest tin, first cast into an ingot, then laminated to a certain extent, and afterwards beat out with a hammer. Tin is used for tinning copper, iron, &c. It adheres strongly to the surface of iron: thin sheets of which coated with it constitute *tin-plate*, or white iron, of which so many articles in domestic use are made. The iron is coated with tin in order to prevent its rusting. Tin-foil coated with mercury, forms the reflecting surface of looking-glasses. A compound of tin and gold, the *purple of Cassius*, gives fine shades of purple to stain glass and artificial gems. Oxide of tin is an ingredient in the white and yellow glazes of pottery, and, fused with the materials of flint, forms *enamel*. Nitrate of tin is the basis of the scarlet employed in dying wool, and many bright colours used by the calico-printer and cotton-dyer. In 1858, the mines of Cornwall produced 10,618 tons of ore; from which 6,920 tons of tin were obtained. Of this, the exports, wrought and unwrought, were of the value of 1,660,556*l*. In the same year, 628 tons of tin-ore were imported, and 59,115 tons of tin.

TIN'CAL, an impure biborate of soda (borax) imported from Thibet, Persia, and China. Borax is prepared from it.

TINC'TURE (*tinctura; from tingo*, I moisten: *Lat.*), in Medicine, a spirituous solution of such vegetable and animal substances as are soluble in rectified or proof spirit. The virtues of many vegetables are extracted almost equally by water and rectified spirit; but, in their aqueous and spirituous tinctures, there is this difference —that the active parts in the former are blended with a large proportion of innate gummy matter, on which their solubility in this menstruum in a great measure depends; while, in the latter, they are almost free from gum. *Tinctures*, in Heraldry, refer to the colours of the shield, and are of three kinds: metals, colours, and furs. The metals are *or* (gold), *argent* (silver); the colours, *gules* (red), *azure* (blue), *sable* (black), *vert* (green), *purpure* (purple), *sanguine* or murrey (dark blood red), and *tenny* (orange); the chief furs are *ermine* and *vair*. They are thus expressed in engravings: *or* by small points; *argent* by a plain surface; *gules* by vertical lines; *azure* by horizontal lines; *sable* by vertical and horizontal lines crossing one another; *vert* by diagonal lines from right to left; *purpure* by diagonal lines from left to right; *tenny* by vertical lines crossed by diagonal lines from right to left; and *sanguine* by diagonal lines crossing one another.

TIRAILLEURS (marksmen: *Fr.*), in the Military art, a name given to a species of infantry seldom intended to fight in close order, but generally dispersed, two and two, always supporting each other, and usually skirmishing in front of the line. They must be particularly expert in their movements: so as to collect quickly into masses at the sound of the bugle; to disperse again with equal expedition; and to act constantly with the whole army. They were introduced by the French during the wars of their revolution.

TIS'RI, the first month of the Hebrew civil year, and the seventh of the ecclesiastical; answering to a part of our September and a part of October.

TIS'SUE, cloth interwoven with gold or silver, or with figured colours.——In Anatomy, the parts of which organized bodies are composed. These parts are made up of cells of different shapes and texture, differently put together. There are, for example, the osseous tissue, the muscular tissue, the nervous tissue, &c.

TITAN'IUM, in Mineralogy, a metal of an orange red colour, first found in Cornwall. It occurs in different states of oxidation. The minute copper-coloured crystals sometimes found in the slag of the iron-smelting furnaces are pure titanium. It is very infusible; will scratch glass, but not crystal; it resists the action of air and acids; but is oxidized by nitre, at a red heat. Its spec. grav. is 5·8. It has been found in Italy and New Zealand along with iron sand, which has been ejected from volcanoes.

TITHES (*teotha*, tenth: *Sax.*), in Ecclesiastical law, the tenth part of the increase annually arising from the profits of land and stock, allotted to the clergy for their support. The custom of paying tithes, or of offering a tenth, has not only been practised under the Jewish law, and by Christians, but we also find something like it among the heathens. The Babylonians and Egyptians gave their kings a tenth of their revenues. The Romans offered a tenth of all they took from their enemies to the gods; and the Gauls, in like manner, gave a tenth to their god Mars. Tithes are personal, predial, or mixed; *personal*, when accruing from labour, art, or trade; *predial*, when arising from the earth, as hay, wood, and fruit; and *mixed*, when accruing from beasts, which are fed off the land.——Tithes, also, are either great or small. The *great*, or parsonage tithes, belong to the rector; the *small*, or vicarage tithes, to the vicar. The great tithes often belong to a lay impropriator or to a college. By a recent enactment, the tithes have been changed into a rent-charge, which is never personal, but apportioned among the lands of the parish, to be paid by their occupiers; and recoverable by holding the lands until they are paid. This is not fixed, being for each year the price of a certain quantity of corn, at the average of the seven years immediately preceding.

TI'THING, a community of ten men, into which all England was divided in the time of the Saxons. [See TYTHING.]

TOAD (*tathe: Sax.*), the name of tailless Batrachian reptiles belonging to the family *Bufonidæ*. The common toad of Britain, *Bufo vulgaris*, was formerly supposed to be venomous, but now considered harmless. It has a thick squat body covered with warts or tubercles, and a fetid milky juice exudes from a protuberance, studded with pores, behind each eye. Toads are capable of living a long time without food, and have been known to remain (if the repeated instances which have been given are to be relied on) whole years in walls, hollow trees, in the earth, or even when artificially enclosed with plaster. Dr. Buckland, however, states, in reference to a number of experiments which he made on the vitality of toads enclosed in wood and stone: 'It seems that toads cannot live a year excluded totally from atmospheric air, and that they cannot survive two years entirely excluded from food; and there is a want of sufficiently minute and accurate observation in those so frequently recorded cases, where toads are said to be found alive within blocks of stone and wood, in cavities that had no communication whatever with the external air.'

TOAD'-STONE, in Mineralogy, a dark brown basaltic amygdaloid, composed of basalt and green earth, and containing oblong cavities in which is calcareous spar.

TOAD'STOOL, the popular name of various inedible funguses which resemble mushrooms in shape.

TOBAC'CO, the *Nicotiana tabacum* of botanists, nat. order *Solanaceæ*, a herbaceous plant which flourishes in America and all temperate climates, and is remarkable for its acrid and narcotic properties. Its name is probably derived from Tobaco, in the province of Yucatan, where it was first found by the Spaniards. It is much used for smoking; and, when pulverized and otherwise prepared, as snuff. When first used it sometimes occasions vomiting; but the practice of using it in any form soon conquers distate, and forms a relish for it that is strong and almost invincible. It is believed to have been introduced into England by Sir Francis Drake and Sir Walter Raleigh, and we may well be surprised that the discovery in America of a nauseous and poisonous weed of an acrid taste and disagreeable odour, in short, whose only properties are deleterious, should have had so great an influence on the social condition of all nations, that it should have become an article of most extensive commerce, and that its culture should have spread more rapidly than that of the most useful plants. The recent leaves have very little smell or taste; but, when dried, their odour is strong, narcotic, and somewhat fetid; their taste, bitter and extremely acrid. When distilled, they yield the essential oil on which their virtue depends, and which is said to be a virulent poison. Tobacco is extensively cultivated in France and other European countries, in the Levant and India; but the tobacco of Cuba and the United States is considered the best. Tobacco was first brought to France in 1560 by Nicot, from whose name has been formed the botanical name of the genus; and, in 1586, Sir Francis Drake introduced the plant to the English. In 1859 the quantity of tobacco imported into Great Britain and retained for home consumption amounted to nearly 34,800,000 lbs.

TODDY, the juice obtained by wounding the flower spathes, or trunks, of the cocoanut palm and other palms. When fermented it becomes arrack.

TO'GA (*Lat.*; from *tego*, I cover), in Antiquity, a robe without sleeves, worn over the *tunica* in time of peace. It was like a large cloak, and was the distinguishing badge of a Roman citizen. The variety in the colour, the fineness of the wool, and the ornaments attached to it, indicated the rank of the wearer. Its colour was ordinarily that of the wool undyed, but it was of a purer white when worn by candidates; but, in time of mourning, it was made of wool naturally black. An embroidered toga, called *toga picta*, was worn by generals when they triumphed. The chief dignitaries of the state wore a purple band affixed to its edge; it was then called a *toga prætexta*. The dress of matrons was the *stola*, the toga being worn only by women of bad character. Under the emperors the toga went out of fashion.

TOISE, a long measure in France, containing six French feet; equivalent to 1·94904 metres, or 6·3945925 English feet.

TOKAY', a kind of wine produced at Tokay in Hungary, made of white grapes. It is distinguished by its aromatic taste; is not considered good till it is three years old, and it continues to improve as long as it is kept. It is the only wine which is drunk by preference in the turbid state.

TOKEN, a small coin, in copper, brass, or lead, formerly issued by corporations, guild companies, and tradesmen for local circulation before the State undertook to provide a coinage of copper. 'Tokens were issued, says Mr. W. Boyne, 'to such an extent that it is presumed 20,000 varieties were coined in England, Wales, and Ireland. It was not until 1672 that farthings, struck at the Mint, of similar size to those of the present day, were ready for circulation, when tokens were suppressed by a stringent order of the king.'

TOLERA'TION (*toleratio*, an enduring: *Lat.*), in a general sense, the allowance of that which is not wholly approved; but more especially, the allowance of religious opinions and modes of worship in a state, when contrary to or different from those of the established church or belief. The first Toleration act in England was passed in 1689; the Roman Catholic Emancipation act, in 1829, and some subsequent acts have placed dissenters on an equality with members of the established church, except as regards a few of the highest offices; even Jews are not now precluded from an enjoyment of civil rights, on account of their religion.

TOLL (*tollo*, I take: *Lat.*), the name generally given to the duties imposed on travellers and goods passing along roads, bridges, &c. It is sometimes taken by a person for every beast driven across his ground, being then called *toll-traverse*.——Toll, the payment made to the corporation of a town, or the lord or owner of a market or fair, on the sale of certain commodities.

TOMA'TO, or LOVE APPLE, the fruit of several species of *Lycopersicum*, nat. order *Solanaceæ*. They are natives of South America, but are now cultivated in many other places on account of the fruit, which is employed as an ingredient in sauces.

TOM'BAC, a species of brass, with excess of zinc; if arsenic is added, it forms *white tombac*.

TOMEN'TOUS (*tomentum*, a stuffing for cushions: *Lat.*), in Botany, downy; or covered with hairs so close as scarcely to be discernible.

TONE (*tonos*, a note, or tone: *Gr.*), the degree of elevation of any sound: its acuteness or gravity.——Musical Tones differ from those of common speech chiefly by being more prolonged, so as to give the ear a more decided perception of their height, formation, and relation to each other. There are two kinds of tones, major and minor. The *tone major* is in the ratio of 8 to 9, which results from the difference between the fourth and fifth. The *tone minor* is as 9 to 10, resulting from the difference between the minor third and the fourth.——Tone, in Medicine, that state of organization in a body, in which the animal functions are healthy and performed with due vigour. Tone in its primary signification is *tension*, and tension is the primary indication of strength. Hence its application to the natural healthy state of the animal organs.

TONGUE (*tung: Sax.*), in Anatomy, a soft, fleshy viscus, very movable in every direction, situated in the cavity of the mouth, and constituting the organ of taste. It is also an instrument of deglutition, and is a very important aid to pronunciation.

TON'IC (*tonos*, a tone: *Gr.*), in Music, the principal note of the key; upon it all regular melodies depend; and with it all of them terminate, as far as the chief melody is concerned, the inner parts of the harmony concluding on the third or *mediant*, and the fifth or *dominant*. The name is applied also to the octaves above and below the key-note.

TON'ICS, medicines that increase the tone of the muscular fibre, and give vigour and action to the system. Preparations of iron and quinine are amongst the best known tonics.

TON'NAGE, the number of tons which a vessel may safely carry. Formerly the tonnage for the payment of dues was calculated on principles which gave an advantage to vessels badly proportioned, that is, having an excess of breadth. But at present it is calculated on more scientific principles.

TON'QUIN or TONKA BEAN, the seed of a large leguminous tree, the *Dipterix odorata* of botanists, growing in the forests of Brazil. The legume is single-seeded, and can only be obtained when it has fallen to the ground. The seed is used for scenting snuff.

TON'SILS (*tonsillæ: Lat.*), in Anatomy, two remarkable glands, one on each side of the mouth, near the uvula; and in popular language called *almonds of the ears*. Their use is to secrete a mucous humour for lubricating the passages; and they have several excretory ducts opening into the mouth.

TON'TINE, a sort of increasing life annuity; or a loan given by a number of persons with the benefit of survivorship. Thus an annuity is shared among a number, on the principle that the share of each, at his death, is enjoyed by the survivors, until at last the whole goes to the last survivor, or to the last two or three, according to the terms on which the money is advanced. The name is derived from its inventor Laurence *Tonti*, a Neapolitan.

TOOTH'ING, in Architecture, bricks left alternately projecting, at the end of a wall; that they may be bonded into the continuation, when it is carried up.

TO'PAZ (*topazion: Gr.*), a gem or precious stone, very generally of a fine yellow or gold colour. It sometimes occurs in masses, but more usually crystallized in rectangular óctahedrons. The *oriental topaz* is most esteemed; its colour borders on the orange. The *occidental*, or that found in Peru, is of a softer substance, but its colour is nearly the same. The Brazilian topaz becomes rose red, but the Saxon loses its colour, by heat. This gem consists of silica, alumina, and fluoric acid.

TOPE, an Indian word for Buddhist structures, in the shape of pillars, towers, or tumuli, erected as memorials of victory or miracles, or as receptacles for relics. The word is also applied by travellers in India to groves of trees, which often afford shady halting-places.

TO'PHUS (*Lat.*), in Mineralogy, a genus of calcareous earths, which are porous and without lustre, and consist principally of carbonate of lime. Its origin is due to precipitation from water.

TOPOG'RAPHY (*topographia*, from *topŏs*, a place; and *grapho*, I write: *Gr.*), the accurate description of some particular place or tract of land. Topography goes into minute details which geography does not enter upon.

TORNA'DO (*Span.* from *torno*, I turn; *Lat.*), a violent gust of wind, or a tempest, distinguished by a whirling motion. Tornadoes are usually accompanied with thunder, lightning, and torrents of rain; but they are of short duration.

TORPE'DO (*Lat.*, literally numbness), the name given to certain fishes possessing electrical powers allied to the rays. They are also called cramp fishes, and electric rays, and are distinguished by the short and somewhat fleshy tail, and the nearly circular disc formed by the body. The electrical apparatus, which has rendered the torpedo so celebrated, consists of small membranous tubes, disposed like honey-comb; and divided, by horizontal partitions, into small cells, which are filled with mucous matters. By exercising this power, the torpedo is enabled to procure its prey, and to protect itself against enemies. Whatever animal attempts to lay hold of it receives a sudden paralysing shock; and small fishes, it is said, are completely stunned on approaching it. One species has been taken on the British coast, but it is very rare.

TORREFAC'TION (*torrefacio*, I make dry by heat: *Lat.*), in Metallurgy, the operation of roasting ores.——In Pharmacy, the drying or roasting of drugs on a metallic plate, till they are reduced to the state desired.

TORRICEL'LIAN VACUUM, in Physics, the vacuum produced by inverting a tube of sufficient length, hermetically sealed at one end, and filled with mercury, or any other fluid, in a vessel containing the same fluid; and allowing the fluid in the tube to descend, until its weight is counterbalanced by that of the atmosphere. The apparatus will constitute the essential portion of a barometer, and was invented by Torricelli. [See BAROMETER.]

TOR'RID ZONE, (*torridus*, parched: *Lat.*), in Geography, that region of the earth included between the tropics, where the sun is vertical at some period of the year, and where the heat is always great. It is 47°, or 705 geographical miles in width, and is intersected by the equator.

TOR'SION BAL'ANCE (*torsi*, a twisting: *Lat.*), an instrument intended for measuring the intensities of electric or magnetic forces, by establishing an equilibrium between them and the force of torsion. [See ELECTROMETER, TORSION.] The force of torsion is inversely proportional to the length of the wire used, and inversely to the fourth power of its diameter. Brass wire is better than iron; but spun glass is better than either.

TOR'SO (*Ital.*), the trunk of a statue, mutilated of head and limbs.

TOR'TOISE, the name given to those shielded reptiles which live on land or in fresh-water; those which live in the sea being called TURTLES [which see]. The most remarkable features of the tortoises is that their ribs and breast-bone are formed into a bony box with openings in front and behind. Through the front opening the head and fore legs protrude, and through the posterior opening the hind legs and tail. This box is composed of plates which vary in shape in the different species. Their jaws are destitute of teeth and are more like the bill of a bird than the mouth of a quadruped. They are possessed of lungs and are oviparous. The land-tortoises feed on vegetables; one species, the *Cistudo europœa*, is a native of the South of Europe, and lives to a great age.

TOR'TURE (*tortura: Lat.*), the infliction of pain on an accused person, for the purpose of extorting a confession of guilt, or the revelation of accomplices. The Greeks and Romans practised it with regard to slaves; and not unfrequently whole families of these unfortunate people were subjected to it, when an atrocious crime, such as the murder of their master, was committed. It has been used in various countries of modern Europe, and even in England. [See QUESTION.]

TO'RUS (*Lat.*), in Architecture, a round moulding in the bases of columns, resembling the astragal in form, but larger.

TO'RY, in British history, the name given to a political party opposed to the *Whigs*, and considered as adhering to the ancient constitution of England. The word *Tory* is Irish, and was formerly applied to a class of depredators in that country; but the distinctions of *Tory* and *Whig* (as political partisans) were not known before the year 1678, in the reign of Charles II., when those who believed that the Roman Catholics conspired against the king and state, as deposed by Titus Oates, were called *Whigs*, and those who disbelieved it, *Tories*. Of late years the term *Conservatives* has been adopted by the Tories, as tending to convey the best explanation of their principles.

TOUCAN', the name given to scansorial birds of the genus *Rhamphastos*, inhabiting tropical America. They are remarkable for having large cellular beaks, and long, feather-like tongues. They derive their name from their cry, which resembles the word *Tucano*.

TOUCH (*toucher*, to touch: *Fr.*; from *tango: Lat.*), one of the five senses, the organs of which are the nervous papillæ of the skin. The term *touch* is most correctly applied to the sensibility which is diffused over the surface of the body. Touch exists with the most exquisite degree of sensibility at the extremities of the fingers and in the lips.

TOUCH'-NEEDLE, small bars of gold, silver, and copper combined together in all the different proportions and degrees of mixture. These are used by assayers and refiners, in the trial called the *touch*, to discover the purity of any piece of gold or silver by comparing the mark it leaves on the touchstone with those of the bars.

TOUR'MALINE, the *Lyncurium* of the ancients. It is a more perfect form of *schorl*. The transparent coloured kinds are sometimes cut into ringstones, and some of them are used in experiments on the polarization of light. Tourmaline consists of silica, alumina, and soda, with a little oxide of manganese and iron.

TOUR'NAMENTS, martial sports, where knights displayed their gallantry and adroitness, by encountering each other on horseback; the weapons being lances with blunt heads of iron, or the lance and sword used in war—these latter being termed *arms à l'outrance*. 'Impartial taste,' says Gibbon, 'must prefer a Gothic tournament to the Olympic games of classic antiquity. Instead of the naked spectacles, which corrupted the manners of the Greeks, the pompous decoration of the lists was crowned with the presence of chaste and high-born beauty, from whose hands the conqueror received the prize of his dexterity and courage.'—One solitary attempt to imitate the jousts and tournaments of former days in this country was made in recent times at the expense of the late Earl of Eglintoun; but its success was not such as to encourage a repetition of it. Tournaments are still exhibited at the court of Wurtemburg.

TOUR'NIQUET (*Fr.*), a surgical instrument for stopping the flow of blood after an amputation. It is a kind of bandage, straitened or relaxed with a screw.

TOW'ER (*tor*: *Sax.*; from *turris*: *Lat.*), in Architecture, a building raised to a considerable elevation, and consisting of several stories. Towers are either round or square, and they are flat on the top, by which they are distinguished from spires or steeples. Before the invention of guns, places were not only fortified with towers, but attacked with movable towers mounted on wheels, which raised the besiegers to a level with the walls.——*Tower of London.* This ancient edifice stands on the north bank of the Thames, at the eastern extremity of the city. The oldest part, the central White tower or Keep, was built by William I. about 1070. The space enclosed by the walls measures twelve acres five roods, and the circumference on the outside of the ditch is 3156 feet. On the south side of the Tower was an arch called the *traitor's gate*, through which state prisoners were formerly brought from the river. Near the site of the traitor's gate is the *bloody tower* in which it is supposed the princes, Edward V. and his brother, were smothered by order of Richard III. In the south-east enclosure were the royal apartments: for the Tower was a royal palace for nearly 500 years. James I. was the last sovereign who resided here. The regalia are kept at the tower, and are shown, with the other curiosities of the place, to the public.

TOW'ERS, ROUND, remarkable structures in Ireland of great antiquity and of unknown origin, varying from 80 to 120 feet in height. They are cylinders on the frusta of cones, having a door eight or ten feet from the ground; and, at the top, narrow openings turned towards the cardinal points. There are sixty-two of them in Ireland, and two in Scotland. They have generally been considered as, in some way, connected with an ancient religion; and there have been a number of hypotheses regarding their object.

TOXICOL'OGY (*toxikon*, poison; and *logos*, a discourse: *Gr.*), that branch of science which is concerned with poisons; their nature, effects, and antidotes. [See POISONS.]

TRA'CHEA (*Lat.*; from *tracheia*: *Gr.*), in Anatomy, the *windpipe*, a cartilaginous and membranous canal, through which the air passes into the lungs. The operation of making an opening into the windpipe is hence called *tracheotomy*. The words *laryngotomy* and *bronchotomy* are also used to express the same thing.

TRA'CHEOCELE (*trachia*, the windpipe; and *kēlē*, a tumour: *Gr.*), in Medicine, an enlargement of the thyroid gland; bronchocele.

TRA'CHYTE (*trachus*, rough: *Gr.*), a species of ancient lava, often porphyritic, and, when it contains hornblende and augite, passing into those varieties of traps which are termed Basalt, Greenstone, Dolerite, &c. Trachyte is usually of a light grey colour.

TRAC'TION (*tracto*, I drag about: *Lat.*), the act of drawing, or state of being drawn. This word has latterly come much into use, in its primary sense, in reference to the draught on railways, canals, &c.——ANGLE OF TRACTION, that which the direction of the power makes with a given plane.

TRAC'TION EN'GINES, locomotive steam engines, constructed for the purpose of drawing loads upon common roads. The leading principle of traction engines is the provision of a large surface for the tractive power to act upon, so as to prevent the wheels sinking into the ground. Various plans have been adopted. In one the wheels are simply made with broad tyres. In another the engine lays down and then takes up pieces of wood or shoes, upon which the wheels run. In a third, a series of rails hinged together and carried by a separate pair of wheels are employed. The driving wheels of the engine are so arranged that they run upon the rails laid down for them by the carrier wheels.

TRADE, the business of buying and selling, comprehending every species of exchange or dealing. It is, however, chiefly used to denote the barter or purchase and sale of goods, wares, and merchandise, either by wholesale or retail. *Foreign trade* consists in the exportation and importation of goods, or the exchange of the commodities of the different countries. *Inland* or *home trade* is the exchange or buying and selling of goods within a country. The word *trade* has also a more limited signification, designating the business which a person has learned, and which he either carries on or is employed in; as, the *trade* of a carpenter, a smith, &c. The liberal arts, learned professions, and agriculture, are not included.

TRADE MARK, the peculiar figure or design with which a manufacturer stamps or labels his goods in order that they may be recognised in the market. By the Merchandise Marks' Act, which passed the Legislature in 1862, the forging or counterfeiting any trade mark and other dealings with trade marks, with intent to defraud, are made misdemeanours, and are punishable by imprisonment or fine, and all articles to which a forged trade mark is attached are forfeited to the crown. Colourable alterations and imitations of a trade mark are treated as forgeries, and penalties are imposed on persons who sell or expose for sale any article with a forged trade mark, which he shall know to be forged, or with a trade mark wrongfully applied, with a knowledge of the misapplication; also on persons who mark, with intent to defraud, upon any article any false description respecting the number, quantity, measure, or weight of such article, or of the place or country in which such article shall be made, or falsely indicating any article to be the subject of an existing patent.

TRADE-WINDS, easterly winds which constantly prevail, with slight variations, in certain regions within the tropics. The trade-winds, in the Atlantic and Pacific oceans, extend to about 28° of latitude each side of the equator; so that a ship, after passing 30°, may every day expect to meet them. But, on first entering them, they will be found to blow from the east, or even a little southerly; and, as the vessel advances, to draw round gradually to north-east. In the East Indies the trade-winds are periodical, and are called *monsoons*. The trade-winds are caused chiefly by the comparatively high temperature of the torrid zone, and the rotation of the earth from west to east. The heated air ascends, and is replaced by air from the neighbourhood of the poles. This would have a direction from north to south, or vice versâ, according to the pole, whence it comes; but, as the velocity of rotation of the airs near the poles is less than that at the equator, the air from the poles, when approaching the equator, is left behind, during the earth's rotation; it has, therefore, two motions, one from the poles to the equator, the other in opposition to the earth's motion, or from east to west; and, therefore, in accordance with the laws of motion, its direction is compounded of both; that is, its direction is towards the north-west or south-west; and the resulting winds are north-easterly or south-easterly. The same causes modify the tidal current. [See TIDES.]

TRADI'TION (*traditio;* from *trado*, I transmit: *Lat.*), that which is handed down from age to age by oral communication; or, the delivery of opinions, doctrines, practices, rites, and customs from father to son, or from ancestors to posterity. There is nothing which requires greater caution than the credence we give to traditionary information. Every person, every country, every age, involuntarily gives a colouring to facts; to say nothing of intentional misstatements. How many pure inventions creep into notice, and soon become widely repeated and believed, either because they suit the purposes of a party, or because they are presented with an air of credibility! It therefore becomes all persons, but more especially the historian, to examine as far as he is able into the origin of every statement, and the character and situation of those on whose authority it rests. 'Historical evidence, like judicial evidence, says Sir G. C. Lewis, 'is founded on the testimony of credible witnesses. Unless these witnesses had personal and immediate perception of the facts which they report, unless they saw and heard what they undertake to relate as having happened, their evidence is not entitled to credit. As all original witnesses must be contemporary with the events which they attest, it is a necessary condition for the credibility of a witness that he be a contemporary; though a contemporary is not necessarily a credible witness. Unless therefore an historical account can be traced, by probable proof, to the testimony of contemporaries, the first condition of historical credibility fails.' If what is called history be examined with reference to these views, how much is there in the early accounts of every nation which must be rejected without hesitation. If the statements are tainted with suspicion from their inherent improbability; if the accounts are numerous and discrepant, no one having a stronger claim on our attention than any other; if there is an entire absence of contemporary witnesses, documents or inscriptions, it must be evident that we are compelled to withhold our belief from much that passes under the name of history.—— In matters of religion the Jews pay great regard to *tradition;* so also do the Roman Catholics—the latter understanding by the term, sacred truths, supposed to have been orally communicated by Christ and the apostles, which, by the assistance of the Holy Ghost, were preserved in the church from one generation of bishops to another. A reverence for tradition is therefore taught in all Roman Catholic catechisms; and it is the foundation on which they believe in their rites and the characteristic parts of their religious worship: considering it of equal authority with the Scriptures themselves.

TRAG'ACANTH (*tragos*, a he goat; and *akantha*, a thorn: *Gr.—goat's thorn*), a gum which exudes from some spiny species of *Astragalus*, nat. ord. *Leguminosæ*, which grow wild in warm climates. Tragacanth is brought chiefly from Turkey, in small contorted pieces resembling worms; and that which is white, clear, smooth, and vermicular is the best.

TRA'GEDY (*tragōdia;* from *tragos*, a goat; and *ode*, a song: *Gr.*), a drama representing some grand and serious action, and generally terminating in some fatal event. The name is supposed to have originated in the custom of leading about a goat, in procession, at the festival of Bacchus; in whose honour these choral odes, which formed the groundwork of Attic tragedy, were sung, or from a goat being the prize.

TRAGI-COM'EDY, a dramatic piece partaking of the nature both of tragedy and comedy.

TRAJEC'TORY (*trajicio*, I throw down: *Lat.*), the curve described by a body in space. The orbits of the planets would be elliptical but for the disturbing forces which they exert on each other; and the path of a projectile would be a parabola, but for the resistance of the air.

TRAMON'TANE (*transmontanus: Lat.*), lying beyond, or on the farther side of the mountains; applied, particularly by the Italians, to such as live north of the Alps.

TRANCE (*transe: Fr.*), a state in which the voluntary functions of the body are suspended; and the mind is possessed by visions.

TRANSAL'PINE (*transalpinus*, beyond the Alps: *Lat.*), lying to the north or west of the Alps: as, *Transalpine* Gaul: opposed to *Cisalpine*, as understood by the Romans.

TRANSCENDEN'TAL (*transcendo*, I climb over: *Lat.*), in Philosophy, according to the definition of Kant, 'that knowledge which occupies itself not so much with objects as with the way of knowing those objects:' or, 'the philosophy of the pure, merely speculative reason, from which the practical is separated.'——*Transcendental*, in Algebra, a quantity which cannot be represented by an algebraic equation, having a finite number of terms, with determinate indices. Thus: a^x x^x log. x, &c.——A *transcendental equation* is one containing such expressions: and a *transcendental curve*, one defined by such an equation.

TRAN'SCRIPT (*transcriptus*, transferred in writing: *Lat.*), a copy of any original writing; particularly that of an act or instrument inserted in the body of another.

TRAN'SEPT (*trans*, across; and *septuus*, an inclosure: *Lat.*), in Architecture, that aisle of ancient churches, which extends across the nave and main aisles.

TRANS'FER (*transfero*, I carry over: *Lat.*), in Commerce, an act by which a person surrenders his right, interest, or property in anything to another.

TRANSFU'SION (*transfusio*, a pouring from one vessel to another: *Lat.*), in Medicine, the act or operation of transferring the blood of one animal into the vascular system of another, by means of a tube. It was at one period supposed, that in cases of great loss of blood from hæmorrhage, and in certain cases of disease, that the blood belonging to the human body might, with great benefit, be replaced by that of other animals. At first, the trials made appeared to be successful; but afterwards they were attended with bad, and in some instances fatal, results.

TRAN'SIT (*transitus*, a passage: *Lat.*), in Astronomy, the *culminations* or passage of a heavenly body across the meridian of a place. The determination of the exact time at which this happens is of the greatest importance: as, by means of it, the differences of right ascensions, and therefore the relative situations of the fixed stars, &c., are ascertained. It is observed, by means of the *transit instrument* [which see]. Also, the passage of the inferior planets, Mercury and Venus, across the sun's disc. When a smaller body passes behind a larger, it is said to suffer an *occultation*.

TRANSIT INSTRUMENT. An instrument intended for the observation of transits. It consists of a telescope firmly attached to a horizontal axis, the ends of which are directed to the east and west points of the horizon. A system of three, five, and sometimes seven vertical and equidistant wires of extreme minuteness, are placed in the focus of the eye piece; and the middle one is an exact representation of that part of the meridian to which the telescope is pointed. When, therefore a star passes the middle wire, it is in the act of culminating; and the instant this occurs, it is noted on a clock, or chronometer. The time at which stars should pass any meridian, whose longitude is known, may be ascertained from the *nautical* almanack; which gives the time of their passing the meridian of Greenwich, and thus the *clock error*, in any observatory, may be determined and corrected. Finding, by the transit instrument, the exact interval of sidereal time between the transits of the different stars, we determine their right ascensions; but to ascertain the place of any star, we require to know also its *polar distance*, which is found by the *mural circle* [which see]. A transit instrument and mural circle are, therefore, indispensable to every observatory.

TRANSI'TION (*transitio*, a passing over *Lat.*), in Rhetoric, is of two kinds. The first is when a speech is introduced abruptly; as when Milton gives an account of our first ancestors' evening devotions:—

Both turn'd, and under open sky adored
The God that made both air, sky, earth
and heaven.—
——Thou also madest the night,
Maker omnipotent, and Thou the day.

The second is when a writer suddenly leaves his subject, and passes to another, which is different at first view, but which serves to illustrate what he says.——In Music, a change of key from major to minor, or the contrary.

TRANSI'TION ROCKS (same *deriv.*), in Geology, a term formerly applied to the older secondary series, from a supposition that they were formed when the world was passing from an uninhabitable to a habitable state.

TRANS'ITIVE (*transitivus*, passing over: *Lat.*), in Grammar, an epithet for a verb expressing an action which passes from the agent to an object; from the subject which *does* something, to the object on which it is *done*.

TRANSLU'CENT (*translucens*, shining through: *Lat.*), in Mineralogy, an epithet by which is designated the power of transmitting rays of light; but not so as to render objects distinctly visible.

TRANSMIGRA'TION (*transmigratio*, literally, a removing from one country to another, *Lat.*), the Pythagorean doctrine of the passing of a soul from one body into another. A belief in this, under various modifications, has existed in different ages of the world, and among various nations. In the Indian doctrine of *metempsychosis*, those who spend religious lives do not pass through different stages of existence, but proceed at once to reunion with the Supreme Being.

TRANSMUTA'TION (*transmutatio: Lat.*), the change of one substance into another of a different nature. The transmutation of base metals into gold was one of the dreams of Alchemy.——In Chemistry, the transmutation of a substance into one of a different form is both easy and common, as of a gas or liquid into a solid.——In Geometry, the change or reduction of one figure or body into another of the same area or solidity, but of a different form; as of a triangle into a square.

TRAN'SOM, in Architecture, a lintel over a door; or the piece that is framed across a double-light window.——In a Ship, the beam or timber extended across the stern-post, to strengthen the aft part, and give it due form.

TRANSPORTA'TION (*transportatio*, a conveying from one place to another: *Lat.*), in Law, a banishment inflicted for crime. Various localities have, at different times, been selected for this purpose; and returning before the sentence expired was formerly punished with death; but latterly those who did so, and such as assisted them in doing it, were transported for life. Criminals are now punished by condemnation to the penitentiary, transportation having been superseded by penal servitude. No male criminals have been sent to New South Wales or Van Diemen's Land for some time; and females have not been transported at all for many years. From whatever cause, the number of persons condemned to this kind of punishment has diminished. In the years 1850, 1851, and 1852, the number of convicts sentenced to transportation for seven years and upwards was 4,962; while, in the years 1858, 1859, and 1860, the number of sentences to penal servitude was only 2,723, of which but 515 were for periods exceeding six years. The number of prisoners in penal establishments, including Bermuda and Gibraltar, at the date of the last returns, was 8,869. The number of male prisoners received into the penal establishments of the United Kingdom, during the years 1858, 1859, and 1860 was 7,255, and during these years 2,131 were sent from Great Britain to Western Australia, Bermuda, and Gibraltar; but none were sent beyond the seas from Ireland in the same period. The Australian Colonies, generally, are unwilling to receive convicts; those sent to Bermuda and Gibraltar are employed on public works. The cost of sending criminals to Australia was found to be about 80,000*l.* per annum; to Bermuda, 65,000*l.*; and to Gibraltar, 35,000*l.*; in all 180,000*l.* It would most probably be more advantageous to the country, and even to the criminal himself, that he should be sent to a distant region. Reformations in the penitentiary are too often simulated for the purpose of obtaining a remission of punishment; and the *ticket-of-leave* system lets loose on society many persons of the very worst character. The criminal does not dread the penitentiary nearly so much as transportation; he is not sent to a remote and savage wilderness; he may sooner or later obtain an abbreviation of his punishment—and, in point of fact, if not through his own fault, he does obtain it long before the nominal term of his confinement expires. When a convict returns from transportation, he comes back being often a new man, may begin life again, and gradually may attain a respectable position—which indeed was open to him in the land of his exile. But the character of one who leaves a *jail* is ruined irretrievably; he may die of want, and he is nearly certain to join again his evil companions. Hence the commission of so many crimes by those who have been just liberated from confinement. The convict but too often quits the penitentiary more corrupt than he entered it, and far more hardened; for no system, however stringent, has yet succeeded in preventing communications between the prisoners.

TRANSPOSI'TION (*transpono*, I transfer: *Lat.*), in Algebra, the bringing any term of an equation over to the other side.——In Grammar, a change of the natural order of words in a sentence.——In Music, a change in the composition, either in the transcript or the performance, by which the whole is removed into another key.

TRANSUBSTANTIA'TION (*transubstantier*, to change from one substance into another: *Fr.*), in Theology, the supposed conversion or change of the substance of the bread and wine, in the eucharist, into the body and blood of Jesus Christ. This is a main point in the Roman Catholic religion, and is rejected by the Protestants, the former maintaining the transubstantiation to be real, the latter only figurative. The reformed churches interpret the text *hoc est corpus meum*, 'this signifies my body;' but the Council of Trent strenuously contended for the literal sense of the verb *est*, and says expressly, that by *transubstantiation* the body and blood of Christ are truly, really, and substantially present, under the species of bread and wine.

TRANSUMP'TION (*transumptio*, the assuming one thing for another: *Lat.*), in the Schools, a syllogism by concession or agreement; used where a question proposed is transferred to another, with this condition, that the proof of the latter should be admitted for a proof of the former.

TRAPE'ZIAN (from *next*), in Crystallography, having the lateral planes composed of trapeziums situated in two ranges, between two bases.

TRAPE'ZIUM (*trapezion*, literally, a small table: *Gr.*), in Anatomy, a bone of the carpus.——In Geometry, a plane figure contained under four unequal right lines, no two of them parallel.

TRAPEZOID' (*trapezion*, a trapezium: and *eidos*, form: *Gr.*), in Geometry, a plane four-sided figure, having two of the opposite sides parallel to each other. Its area is equal to half the sum of the two parallel sides, multiplied by the perpendicular distance between them.

TRAP-ROCKS (*trappa*, a flight of steps: *Swed.*), in Geology, rocks which frequently occur in large tabular masses, rising like steps, one above another. They are of volcanic origin, and are composed of felspar, augite, and hornblende; the different proportions of these constituents giving rise to many varieties. The whole family of trap-rocks have, on the one hand, a close alliance with volcanic rocks, and, on the other, with porphyry and granite. Where basalt is in contact with gneiss, it becomes nearly compact, and approaches to the character of hornstone; and where greenstone rests on sandstone or clay, these rocks have a red and burnt appearance, and a hardness superior to what they possess in other places. The trappean rocks, when free from vesicular cavities, are valuable for architecture, especially the greenstone trap, which is quarried with little expense.

TRAUMA'TIC (*traumatikos: Gr.*), belonging to wounds.——*Traumatic balsams* and certain balsams, &c., used in old pharmacy.

TRAVEL'LER, in Nautical affairs, a ring or hoop which slides along a space.

TRAV'ERSE (*traverser*, to cross: *Fr.*), in Fortification, a trench with a little parapet for protecting men on the flank; also, a wall raised across a work.——In Law, a denial of what the opposite party has advanced in any stage of the pleadings.——In Navigation, *traverse-sailing* is the mode of computing the place of a ship by reducing several short courses made by sudden shifts or turns, to one longer course.——*Traverse-board*, a small board to be hung up in the steerage of a ship, and bored full of holes upon lines, showing the points of compass. By moving a peg on this, the steersman keeps an account of the number of glasses a ship is steered on any part.——*Traverse-table*, a table used for finding the difference of latitude and departure.

TRAV'ERTIN (*Ital.*), a calcareous stone deposited by springs of water holding lime in solution by an excess of carbonic acid or by heat. It is found in many parts of Italy, where the compacter forms of it are used as building stone [See TUFA.]

TRAVES'TY, or TRAVES'TIE (*travestir*, to disguise: *Fr.*), the burlesque imitation of an author's style and composition. Most travesties purposely degrade the subject treated; though they may be intended either to ridicule absurdity or to convert a grave performance into a humorous one.

TREAD'MILL, a mill which has been introduced into prisons, as an instrument of punishment. It has a large wheel, with steps on its external surface, upon which the criminals are placed. Their weight sets the wheel in motion, and they maintain themselves in an upright posture, by means of a horizontal bar fixed above them, which they hold. The exercise is very fatiguing, and the prisoners have a short respite after being on the wheel for about ten minutes.

TRE'ASON (*trahison: Fr.*), in Law, is divided into *high treason* and *petty treason*. High treason is the greatest crime of a civil nature of which a man can be guilty. In general it is the offence of attempting to subvert the government of the state to which the offender owes allegiance; or of attempting, imagining, or compassing the life of the sovereign, the queen consort, of the heir-apparent of the crown, and certain other serious crimes of a like nature. Treason must be prosecuted within three years from its commission. Information for open and advised speaking must be given within six days. In England, those convicted of treason are usually hanged and afterwards beheaded, the more barbarous and revolting part of the sentence, namely, emboweling and quartering, being dispensed with. But a conviction of treason is visited by forfeiture of lands and goods to the crown, and attainder of blood. This, however, may afterwards be reversed. In treason, all are principals.——*Petty Treason* is the crime of a wife killing her husband, or a servant his master, crimes which are now treated as murder.

TREAS'URER (*tresor*, treasure: *Fr.*; from *thesauros: Gr.*), in Law, an officer to whose care the treasure of the state or of any company is limited.—The *Lord High Treasurer of England* was formerly the third great officer of the crown, but the appointment is now filled by five persons, styled 'the Lords Commissioners of the Treasury;' one of whom is the Chancellor of the Exchequer. The first Lord is usually Prime Minister.

TREAS'URE-TROVE (*trouver*, to find: *Fr.*), in Law, money or any other treasure found secreted under the earth. It belongs to the sovereign or some other who claims by the royal grant, or by prescription. When the owner is unknown coins or other articles found on the surface of the ground, or such things if originally lost by the owner, do not come within the denomination or law of treasure-trove.

TREB'LE, the highest or most acute of the parts in music, and adapted to the voice of females or boys. It is divided into the first or highest treble, and the second or low treble. Half treble, or *mezzo soprano*, is a high counter-tenor.

TREE, a name given to those plants which have permanent woody stems, and rise to the height of 20 feet at least. Some trees live to a great age; some British yews are thought to be from 1200 to 3200 years old. But some specimens of the Baobab, an African tree, are supposed to be 5000 years old.——Groves and woods, in the first ages, were resorted to as temples; and particular trees were supposed to be the residence of certain divinities; thus the Dryads and Hamadryads were believed to be enshrined in oaks. The gods are also said to have taken particular species of trees under their protection. Jupiter, we are told, chose the oak, Venus the myrtle, Apollo the laurel, Cybele the pine tree, Hercules the poplar, Minerva the olive, and Bacchus the ivy and the vine.

TREE-NAIL, a long wooden pin, used in fastening the planks of a ship to the timbers.

TREE-FROG, a small species of frog in North America, which is found on trees, and croaks chiefly in the evening. It differs from the common frog in having the extremity of each toe widened and rounded in a viscous palette which enables them to adhere to the surfaces of bodies.

TRE'FOIL (*trifolium: Lat.*), in Botany, the common name of many plants with ternate leaves: thus the *Trifolium repens*, or white trefoil; *Trifolium minus*, or yellow trefoil; *Medicago lupulina*, or black trefoil; *Lotus corniculatus*, or bird's foot trefoil, &c. They are all used as food for cattle.

TREL'LIS (*treillage: Fr.*), in Gardening, a frame of cross-barred work, or lattice-work, used for supporting plants. It differs from *treillage*, which consists of light posts and rails for supporting espaliers, and sometimes for wall trees.

TREM'OLITE, a mineral of a fibrous texture originally found in the valley of Tremola, on St. Gothard. It consists generally of silica, magnesia, and carbonate of lime.

TRENCHES, or *lines of approach*, in Fortification, ditches cut in oblique zigzag directions, to enable besiegers to approach a fortified place without being exposed to the fire of its cannon. Hence the terms to *open the trenches*, or to break ground for the purpose of carrying on approaches to a besieged place; *mount the trenches*, or to mount guard in the trenches, &c.

TREPANG', an eastern word imported into commerce, signifying a worm-like echinoderm distantly related to the star-fishes and sea hedgehogs. Several species of *Holothuria* are collected in the Indian archipelago, where there are extensive fisheries of the animal, and after being dried are sent to China, where they are employed for culinary purposes, forming one of the dainties of a Chinese table along with birds' nests and sharks' fins. Animals of the same nature are found round our own coasts.

TREPAN'NING (*trepaner*, to trepan: *Fr.*), in Surgery, the operation of perforating the skull and taking out a piece, for relieving the brain from pressure, &c. The instrument used is called a *trepan*. [See TREPHINE.]

TREPH'INE, in Surgery, a more modern instrument than the *trepan* for performing the operation of trepanning. It is a circular or cylindrical saw, with a handle like that of a gimlet, and a little sharp perforator, called the centre-pin.

TRES'PASS (*trespasser*, to transgress: *Fr.*), in Law, any violation of another's rights; as, the unlawfully entering on his premises; but when violence accompanies the act, it is called a trespass *vi et armis*.

TRI'AD (*trias*, the number three: *Gr.*), in Music, the common chord, consisting of the third, fifth, and eighth.

TRI'AL, in Law, the examination of causes before a proper judge, which, as regards matters of fact, are to be tried by a jury; as regard matters of law, by the judge: and as regards records, by the record itself. [See LAW, JURY, &c.]——*New trials*, in civil cases, are granted when the court of which the record is, sees reason to be dissatisfied with the verdict: either because evidence was improperly received or rejected, or the judge misdirected the jury as to the law which applied to the facts; or a party was unfairly surprised; or fresh evidence has been discovered.

TRIAN'DRIA (*tris*, three times; and *anēr*, a male: *Gr.*), one of the Linnæan classes, comprehending plants the flowers of which have three stamens, as the crocus, gladiolus, valerian, &c.

TRI'ANGLE (*triangulum:* from *tres*, three; and *angulus*, an angle: *Lat.*), in Geometry, a figure of three sides and three angles. Triangles are either plane or spherical. A *plane triangle* is contained under three right lines, and a spherical under three arcs belonging to great circles of the sphere. Triangles are denominated from their angles. A *right-angled triangle* is that which has one right angle; an *obtuse-angled triangle* is such as has one obtuse angle; and an *acute-angled triangle* is that which has all its triangles acute. And from their sides, an *equilateral triangle* has three equal sides; an *isosceles triangle* has two equal sides; and a *scalene triangle* has all its sides unequal. *Similar triangles* are those whose angles are equal, and corresponding sides proportional.——*Triangle*, in Music, a small triangular steel instrument, open at one of its angles; and played by striking it with a short bar of the same metal.

TRI'AS, or UPPER NEW RED SANDSTONE, in Geology, a series of strata forming the oldest division of the secondary period, and intervening, therefore, between the Permian and the Liassic groups. It has been divided into the *Upper Trias*, to which the saliferous and gypseous sandstones and slates of Cheshire belong; the *Middle Trias*, or Muschelkalk, which has no representative in Britain; and the *Lower Trias*, which includes the red and white sandstones of Lancashire and Cheshire, and the Bunter-Sandstein of Germany. This threefold division suggested the name of the group (*tria*, three: *Lat.*). All the strata appear to be marine. The salt mines of Cheshire are in the upper triassic beds.

TRIB'UNE (*tribunus*, from *tribus*, literally, the chief officer of a tribe: *Lat.*), in Roman Antiquity, the title of various officers. *A Tribune of the people* was chosen out of the plebeians to protect them against the encroachments and oppression of the patricians, and the attempts of the senate and consuls to lessen or destroy their liberty. Tribunes were first elected after the succession to the *Mons Sacer*, A.U.C. 260. They were not, strictly speaking, magistrates, or invested with magisterial powers, but they exercised a great influence upon public affairs. They had the right to put a negative on the decrees of the senate, and arrest the proceedings of magistrates by the *veto;* and in process of time their influence was increased to such a degree that they endangered the safety of the state.——*Military tribunes*, officers elected in place of the consuls; in consequence of the demand made by the common people to be admitted to a share in supreme power. They were not, however, invested with the full power and honours of the consulate; and besides, were generally selected from the patricians. There were sometimes six, and sometimes three. They were first chosen A.U.C. 310, and continued to be elected, instead of consuls, at intervals for seventy years; after which time there were only consuls, but plebeians were admissible to the office.——*Legionary Tribunes*, or tribunes of the soldiers, were the chief officers of a legion. There were six; and each in turn commanded under the consul; in battle, each led a cohort, or about 1000 men.——*Tribuni Ararii*, tribunes of the treasury.——*Tribuni Fabricarum*, those who had the direction of the making of arms.——*Tribuni Voluptatum*, intendants of the public shows, and other diversions.——*Tribune*, in ancient Architecture, the pulpit or elevated place whence speeches and addresses were delivered. In the French legislative houses the speakers address the assembly from a tribune.

TRICAP'SULAR (*tres*, three; and *capsula*, a small chest: *Lat.*), in Botany, an epithet for such plants as have three capsules to each flower.

TRICLIN'IUM (*Lat.;* from *triklinion: tries*, three; and *klinē*, a couch: *Gr.*), a name given by the Greeks to the room where they supped, because three couches were placed about the table. This name was adopted by the Romans as synonymous with *Cœnaculum*. *Triclinium* is sometimes used for the couch, on which the guests reclined.

TRI'COLOR (*tres*, three; and *color*, a colour: *Lat.*), the national French banner of three colours (blue, white, and red), selected as the emblem of the first revolution. The *Tricolor* has been adopted by Belgium, and is often used as emblematical of liberty.

TRICUS'PIDATE (*tricuspis*, having three points: *Lat.*), in Natural History, an epithet for anything ending in three points.

TRI'DENT (*tridens*, literally having three teeth: *Lat.*), an attribute of Neptune; being a kind of three-pronged sceptre which the fable of antiquity put into the hands of that deity.——*Trident*, among Mathematicians, a kind of parabola, by which Des Cartes constructed equations of six dimensions.

TRIDODECAHE'DRAL (*treis*, three; *dodeka*, twelve; and *hedera*, a base: *Gr.*), in Crystallography, presenting three ranges of faces, one above another, each containing twelve.

TRI'FID (*trifidus*, three cleft: *Lat.*), in Botany, divided into three parts by sinuses with straight margins.

TRIFO'LIATE (*tres*, three; and *folium*, a leaf: *Lat.*), in Botany, having three leaves.

TRIFO'LIUM (same *deriv.*), in Botany, a genus of leguminous plants, including the clovers and some of the trefoils.

TRI'GAMOUS (*treis*, three; and *gamos*, marriage: *Gr.*), a name given by some Botanists to plants containing three kinds of flowers in the same flower-head: males, females, and hermaphrodites.

TRIG'LYPH (*trigluphos*: from *treis*, three; and *gluphē*, a carving: *Gr.*), in Architecture, a member of the Doric frieze, repeated at equal intervals. It consists of two whole, and two half channels, separated by flat spaces, termed *femora*.

TRIGONOM'ETRY (*trigōnon*, a triangle; and *metreo*, I measure: *Gr.*), the art of measuring the sides and angles of triangles. A triangle contains three sides, and three angles; when we know any three of these including, in plane trigonometry, at least one side, the others can be found. Angles are *given*, if their *sines*, &c., are *given*. When this science is applied to the solution of plane triangles, it is called *plane* trigonometry; when to spherical triangles, *spherical* trigonometry. Trigonometry is a most important branch of knowledge. Plane trigonometry enables us to measure, with great ease, inaccessible heights and distances, &c. Spherical trigonometry is indispensable to the astronomers. The Greek astronomers of Alexandria were the inventors of trigonometry.

TRIJU'GOUS (*tres*, three; and *jugum*, a pair: *Lat.*), in Botany, having three pairs. A *trijugous* leaf is a pinnate leaf with three pair of leaflets.

TRIL'LION, in Arithmetic, a thousand times a thousand millions; that is unity in the lowest place of the fifth period to the left of the decimal point. It is very often, though erroneously, considered as a million times a million of millions.

TRIL'OBITES (*treis*, three; and *lobos*, a lobe: *Gr.*), an order of Crustaceans only found in the fossil state, in palæozoic strata; having a body composed of a series of rings and longitudinally divided by two furrows into three lobes. They had a head, a thorax, and an abdomen more or less distinct, and they had a pair of large compound eyes. They were nearly allied to some of the existing *Phyllopoda*. Their food was the smaller aquatic animals, and they lived in vast numbers in the vicinity of coasts in shallow water.

TRIL'OGY (*treis*, three; *logos*, a discourse: *Gr.*), a set of three dramas relating to the same series of events. The three parts of Shakespeare's Henry VI. form a trilogy. The Orestes, Iphigenia in Tauris, and Andromache of Euripides, afford another example.

TRIM'MER, in Architecture, a piece of timber framed at right angles to the joists which are opposite to chimneys, to the well holes of stairs, &c. It receives the ends of the joists, intercepted by the opening.——*Trimming joist*, a joist into which a trimmer is framed.

TRIM'YARIES (*treis*, three; and *mūn*, a muscle: *Gr.*), those bivalves which present three muscular impressions on each valve.

TRINE (*trini*, a set of three: *Lat.*), in Astrology, the aspect of planets placed in three angles of a triangle; in which position they were supposed to be eminently benign.

TRIN'GA, in Ornithology, a genus of grallatorial birds. They have a hind toe; though it is too short to reach the ground; and, in this, are unlike the plovers, in which the hind toe is generally wanting. There are several British species, including the knot, dunlin, stints, and sandpipers.

TRIN'GLE (*Fr.*), in Architecture, an ornament, fixed exactly over every triglyph, under the platband of the architrave. The guttæ or pendant drops hang down from it. ——Also, other small square members.

TRIN'ITY HOUSE, a society incorporated by Henry VIII. in 1515, for the promotion of commerce and navigation, by licensing and regulating pilots, ordering and erecting beacons, light-houses, &c. This corporation is governed by a master, four wardens, eight assistants, and thirty-one elder brothers; besides numerous inferior members of the fraternity, named younger brethren. Many valuable privileges are attached to it, and its revenue amounts to about 140,000*l.* per annum. The hall of the Trinity House is an elegant building, not far from the Tower of London.

TRINO'MIAL (*tres*, three; and *nomen*, a name: *Lat.*), in Mathematics, an epithet for any quantity or root consisting of three terms, united by the sign of addition or subtraction: thus $a + bc - d$.

TRIO (*Ital.*), in Music, a composition consisting of three parts: one of which must make a third with the base, and the other a fifth or octave.

TRIOCTAHE'DRAL (*treis*, three; *oktō*, eight; and *hedra*, a base: *Gr.*), in Crystallography, presenting three ranges of faces, one above another, each range containing eight faces.

TRIŒ'CIA (*treis*, three; and *oikia*, a family: *Gr.*), in Botany, the name of the third order in Linnæus's class *Polygamia:* comprehending such plants as have hermaphrodite (male and female) flowers of the same species, in three distinct individuals.

TRIOLET, a stanza of eight lines, in which, after the third, the first line, and after the sixth, the first two lines, are repeated; so that the first line is heard three times.

TRIO'NES (*Lat.*, literally, the ploughing oxen), in Astronomy, a name for the cluster of seven stars in Ursa Minor, called also *Charles's Wain.*

TRIP'ARTITE (*tripartitus: Lat.*), in Botany, an epithet for a leaf which is divided into three parts down to the base, but not wholly separate.

TRIPE DE ROCHE (*Fr.*), species of lichen belonging to the genus *Gyrophora*, found in arctic regions, upon which famished voyagers are sometimes compelled to feed, and they are frequently the food of Canadian hunters.

TRIPET'ALOUS (*treis*, three; and *petalon*, a leaf: *Gr.*), in Botany, having three petals or flower leaves.

TRIPH'THONG (*treis*, three; and *phthongos*, a sound: *Gr.*) in Grammar, a coalition of three vowels in one compound sound, or in one syllable; as in *adieu*, *beau*.

TRIPIN'NATE, in Botany, an epithet for a species of compound leaf; when a petiole has bipinnate leaves ranged on each side of it.

TRIP'LET, in Poetry, three verses rhyming together.——In Music, notes grouped by threes; when the figure 3 is placed over them they are to be played in the time of two.

TRIP'LE TIME, in Music, a time in which each bar can be divided into three parts. [See TIME.]

TRIPLICATE RATIO (*triplico*, I multiply by three: *Lat.*), in Arithmetic, &c., the ratio of the cubes, of the terms of a simple ratio; thus, $a^3 : b^3$ is the triplicate ratio of $a : b$.

TRIP'OD (*treis*, three; and *pous*, a foot: *Gr.*), in general, anything having three feet.——In Grecian Antiquity, the sacred seat, supported by three feet, on which the priestesses among the ancients used to deliver the oracles.

TRIP'OLI, in Mineralogy, a silicious mineral, originally brought from Tripoli; used in polishing stones and metals. It has a dull argillaceous appearance, but is not compact. It has a fine hard grain, but does not soften by water, or mix with it. The various kinds of Tripoli have been found to consist of the silicious coats of minute organisms, chiefly vegetable.

TRIP'TOTE (*triptōtos: Gr.*), in Grammar, having three cases only.

TRIPYR'AMID, in Mineralogy, a genus of spars, the body of which is composed of single pyramids, each having three sides, and affixed by their base to some solid body.

TRIQUET'ROUS (*triquetrus*, having three corners: *Lat.*), in Botany, an epithet for a fruit or leaf that has three plane sides or faces.

TRIRE'MIS, or TRI'REME (*tremis: Lat.*), in Greek and Roman Antiquity, a galley with three tiers or banks of oars. The rowers are supposed to have been placed on seats one over another, the two lower being separated by a deck.

TRI'SECTION OF AN ANGLE, in Geometry, a problem of great celebrity among ancient mathematicians. An acute or obtuse angle cannot be trisected by plane geometry; but it may be done by means of the conic sections, and some other curves.

TRISMUS (*trizo*, I grind the teeth: *Gr.*), in Medicine, the *lock-jaw.* One species is caused by wounds, or exposure to cold; the other attacks infants during the first two weeks after birth.

TRITER'NATE (*tres*, three; and *terni*, three each: *Lat.*), in Botany, having three biternate leaves; or the divisions of a triple petiole, subdivided into threes.

TRITH'EIST (*treis*, three; and Theos, a God: *Gr.*), in Theology, one who believes that there are three distinct Gods in the Godhead; that is, three distinct substances and essences.

TRIT'ICUM (*Lat.; from tritus*, ground, on account of the mode of preparing it for food), a genus of plants, nat. ord. *Graminaceæ*, to which wheat belongs.

TRI'TON, in the Greek Mythology, a kind of demi-god, half man and half fish. ——*Triton*, in Malacology, a genus of marine molluscs inhabiting univalve shells.

TRI'TONE (*tritonos*, consisting of three tones: *Gr.*), in Music, an interval now usually called a *sharp fourth*; it consists of four degrees, and contains three tones between the extremes. It is divisible also into six semitones: three of them being diatonic and three chromatic.

TRITOX'IDE, in Chemistry, an oxide containing one atom of base and three of oxygen.

TRITURA'TION (*trituratio: Lat.*), in Pharmacy, the act of reducing a solid body into a fine powder; called also *levigation* and *pulverization.*

TRI'UMPH (*triumphus: Lat.; from thriambos*, originally a hymn to Bacchus: *Gr.*), in Roman Antiquity, a public and solemn honour conferred by the Romans on a victorious general; by allowing him a magnificent procession through the city. The triumph was of two kinds, the greater and the less; the latter of which was called an *ovation*. This splendid spectacle was arranged as follows: the whole senate went out to meet the victor, who, being seated in a gilded chariot, sometimes drawn by white horses, and clad in his gold embroidered triumphal robes, was preceded by the kings, princes, and generals whom he had vanquished, loaded with chains, as well as by singers and musicians; and was followed by carefully selected victims, and by the spoils and emblems of the conquered cities and provinces. Lastly came the victorious army, horse and foot, crowned with laurel, and adorned with the marks of distinction they had received, shouting *Io triumphe*, and singing songs of victory, or of sportive raillery. Upon the capitol, the general rendered public thanks to the gods for the victory; caused the victims to be slaughtered; and dedicated the crown which he wore, and a part of the spoils, to Jupiter. All the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places; the general gave a costly feast, and the shouts of the multitude rent the air with their rejoicings.

TRIUM'PHAL ARCH, a grand gate, or archway, erected at the entrance of a town, or in some other public situation, in commemoration of some important event, or in honour of some victorious general. It sometimes consisted of one, at others of two or three, openings; the last kind being the most beautiful. Among the remains of antiquity, Italy can boast of the relics of several triumphal arches; and many beautiful structures of the kind have been erected in modern times.

TRIUMPHALIS CORONA. [See CROWN.]

TRIUM'VIRATE, an absolute government administered by three persons, named *Triumvirs* (*triumviri*, three men: *Lat.*), with equal authority; as that of Augustus, Marc Antony, and Lepidus; which gave the last blow to the Roman republic. For Augustus having vanquished Lepidus and Antony, the triumvirate was soon converted into a monarchy.

TRIVIUM (a place where three roads meet: *Lat.*), a name given in the middle ages to the three liberal arts, grammar, rhetoric, and logic, which were studied together. The other four, arithmetic, music, geometry, and astronomy, being called *quadrivium*.

TROCAR' (*Fr.*), in Surgery, an instrument for making incisions; particularly in the operation of tapping for the dropsy.

TROCHAN'TER (*trōchazo*, I gallop: *Gr.*), in Anatomy, a name given to two apophyses, situated in the upper part of the thigh-bone; they receive the tendons of most of the muscles of the thigh. The *major* process is on the outside, and the *minor* on the inside of the thigh. They receive their name from being chiefly concerned in the act of running.

TRO'CHE (*trochos*, anything round: *Gr.*), a small lozenge or cake, generally consisting of sugar and mucilage, with small quantities of more active substances, and intended to be gradually dissolved in the mouth.

TRO'CHEE (*trochaios;* from *trochos*, a running: *Gr.*), in Greek and Latin poetry, a foot consisting of two syllables, the first long, and the second short.

TRO'CHILUS (*trochilos: Gr.*), in Architecture, a name used by the ancients for a hollow ring round a column, which the moderns call *scotia*.——*Trochilus*, in Ornithology, a genus of *Humming birds*, which see.

TRO'CHITE (*trochos*, anything round: *Gr.*), in Natural History, a kind of figured fossil stone resembling parts of plants, called St. Cuthbert's beads. Trochites are usually of a brownish colour, and break like spar.

TROCH'LEA (a pulley block: *Lat.*), in Anatomy, a cartilage through which the tendon of the trochleary muscle passes.——The *trochleary muscle* is the superior oblique muscle of the eye; the *trochleary nerve*, the nerve which goes to that muscle.

TROGLOD'YTES (*trōglodutes;* from *trōglē*, a hole; and *duo*, I go into: *Gr.*), certain tribes in Ethiopia who are represented by ancient writers as living in subterranean caverns; and respecting whom we have many fabulous stories.

TROM'BONE (*Ital.*), a musical instrument, of which there are three kinds: the bass, the tenor, and the alto. It is extremely powerful; and therefore best suited to grand choruses and other full compositions.

TROOP (*troupe: Fr.*), in Cavalry, a certain number of soldiers mounted, who form a component part of a squadron. It is the same, with respect to formation, as *company* in the infantry.——The word *troops* (in the plural) signifies soldiers in general, whether more or less numerous, including infantry, cavalry, and artillery.

TROPE (*tropos;* from *trepo*, I alter: *Gr.*), in Rhetoric, an expression used in a different sense from that which it properly signifies. It is intended to present an idea in a lively and forcible manner.

TRO'PHY (*tropaion: Gr.*), anything taken and preserved as a memorial of victory; as arms, standards, &c., taken from an enemy. It was customary with the ancients to erect their trophies on a spot where they had gained a victory. At first they consisted of the arms they had taken; but afterwards trophies were formed of bronze, marble, or even gold.——In Architecture, an ornament representing the stem of a tree, charged or encompassed with military weapons.

TRO'PICS (*tropikos*, belonging to a turning round: *Gr.*—the line at which the sun turns back), in Geography, a zone of the earth, 23½ degrees, or about 1600 miles on each side of the equator, over some part of which the sun passes directly vertical two days in the year. It is the hottest, wettest, and most fertile part of the earth; but is less favourable to human life than the temperate zones. Its heats are, however, tempered by winds which constantly follow the sun from east to west, and which, from their convenience to ships, are called *Trade Winds*. In the plains the heat varies from 120 to 80 degrees, and is seldom below 65 ——In Astronomy, parallels of declination drawn through the solstitial points. There are two tropics; the tropic of Cancer, on the north of the equator, and the tropic of Capricorn on the south; each is 23½° from the equator.

TROU'BADOURS, poets who flourished in Provence, from the 11th to the latter end of the 13th century. They wrote poems on love and gallantry; on the illustrious characters and remarkable events of the times, &c., which they set to music and sung: they were accordingly general favourites in different courts, diffused a taste for their language and poetry over Europe, and essentially contributed towards the restoration of letters, and a love for the arts. Each baron, a sovereign in his own territory, invited the neighbouring knights to his castle to take parts in tournaments and to contend in song; at a time when the knights of Germany and Northern France were challenging each other to deadly combat. Thus the verse of the Provençals was lyrical in the highest degree; but it was necessarily superficial, and would lose its chief value if unaccompanied by music. In the 11th and 12th centuries it had attained its highest celebrity; it had spread into Spain and Lombardy; and even German emperors (Frederic Barbarossa), and English kings (Richard Cœur de Lion), composed songs in the Provençal dialect. But the poetry of the Troubadours, as in the course of time it became more common, became degraded to mere ballad-singing; and the few specimens of it that have been preserved, consist of short war-songs and lyrics of pastoral life and love. [See PROVENÇAL.]

TROUT, the *salmo fario* of ichthyologists, in the family *Salmonidæ*, a delicate fish, abounding in many of the rivers of England. It frequents the clearest streams, and has always been the favourite sport of the angler. Trout are prettily coloured, the back being mottled, and the sides dark brown, with yellow spots, which have a scarlet dot in the centre. They seldom exceed four pounds in weight; and are generally between one and two pounds.

TRO'VER (*trouver*, to find: *Fr.*), in Law, a special action upon the case, which may be maintained by any person who has either an absolute or special property in goods, for recovering the value of such goods, against another who, having, or being supposed to have obtained possession of them by lawful means, has converted them to his own use.

TROY'-WEIGHT, the weight by which gold and silver, jewels, &c., are weighed. It is also used in weighing medicines, in experiments in natural philosophy, and in comparing different weights with each other. The pound contains 12 ounces, or 5,760 grains.

TRUCE OF GOD, a suspension of hostilities, often proclaimed during the middle ages, on the authority of the church. It afforded an interval of peace amid those private hostilities, in which every petty baron believed it his right to engage.

TRUCK, the small wooden cap, at the extremity of a flagstaff, or masthead.

TRUCK SYSTEM (*troc*, to give in exchange: *A. Sax.*), a name given to a mode, at one time very prevalent in manufacturing districts, of the employer paying his workmen in provisions, clothes, and other goods, instead of money. In favour of this practice it was argued, that the manufacturer, having the command of capital, was enabled to establish shops, or general *depôts*, from which the working man could supply his family with necessaries at the cheapest rate. But the mechanic had often to pay exorbitant prices for the articles he was compelled to purchase, and was subject to every species of unfair dealing and tyranny by such a system; and, after much discussion, an act was passed for its suppression.

TRUFFLES (*truffe: Fr.*), fungi growing underground, and much prized as condiments in cookery. They are difficult to find; but as the commoner species, belonging to the genus *Tuber*, have a peculiar smell, dogs are trained to discover them. They are usually found in calcareous soil, and are more abundant in France than in England, and still more plentiful in Italy.

TRUM'PET, the loudest of all portable wind instruments, consisting of a tube, generally of brass.——*Hearing trumpet*, or ear trumpet, an instrument, which is used to enable deaf persons to hear sounds, that would otherwise be inaudible to them; it collects and conveys to their ears waves of sound, which would pass off in other directions. It is constructed on the same principle as the speaking trumpet; and, indeed, is that trumpet reversed; though, for convenience, it is often made curved or spiral. ——*Speaking trumpet*, a tube, from six to fifteen feet in length, made of tin, perfectly straight, and having a very large aperture; the mouth-piece being wide enough to admit both lips. By means of this instrument the voice is carried, with distinctness, to the distance of a mile or more. It is used chiefly at sea. The aërial undulations, which would disperse themselves in all directions, are confined by the sides of the instrument; and reflected in a direction parallel to its axis.—— *The feast of trumpets*, a festival among the Jews, observed on the first day of the seventh month of the sacred year, which was the first of the civil year, and answered to our September. The beginning of the year was proclaimed by sound of trumpet.

TRUM'PETER, or *Agami*, the *Psophia crepitans* of ornithologists, a bird of the heron family, which inhabits tropical South America. Its name is derived from its cry. It is easily tamed, and becomes as attached to its owner as a dog.

TRUN'CATE (*truncatus*, mutilated: *Lat.*), in Botany, appearing as if cut off at the tip: as, a *truncate* leaf.

TRUN'NIONS, two knobs which project from the opposite sides of a piece of ordnance, whether gun, mortar, or howitzer; and serve to support it on the cheeks of the carriage.——The *trunnion-ring*, is that ring on a cannon which is next in front of the trunnions.

TRUSS (*trousse*, a bundle: *Fr.*), in Architecture, a framed collection of pieces of timber. [See ROOF.]——In Navigation, a machine to pull a lower yard close to its mast, and retain it firmly in that position. ——In Carpentry and Engineering, a triangular frame used as a support, or a polygonal frame made rigid at the joints and employed for the same purpose.——A bundle of hay or straw, equal to 56 lbs.; six trusses make a *load*.——In Surgery, a bandage or apparatus used in cases of rupture, to keep up the reduced parts, and hinder further protrusion; and for other purposes.

TRUSTEE', in Law, one to whom is confided the care of an estate, money, or business, for the benefit of another.

TRYSOLYMPON'ICA (*Gr.*; from *treis*, three; *Olumpia*, the Olympic games; and *nikē*, a victory), in Antiquity, one among the Greeks who returned three times victorious from the Olympic games; and on whom special honours were conferred by the state.

TU'BA (*Lat.*), a wind instrument, used by the ancient Romans, resembling our trumpet; though of a somewhat different form.

TUBE (*tubas: Lat.*), a hollow cylinder, either of wood or metal, used for the conveyance of fluids, &c. Also, a vessel of animal bodies or plants, which conveys a fluid or other substance.——In Botany, the narrow hollow part of a monopetalous corolla, by which it is fixed to the receptacle.

TU'BERCLES (*tuberculum*, a small swelling: *Lat.*), in Medicine, little tumours which suppurate and discharge pus.——In Natural History, little knobs or rough points. Hence the epithet *tuberculate*.

TU'BEROSE, the *Polyanthes tuberosa* of botanists, a liliaceous plant with white strongly scented flowers, well known in our greenhouses. It is a native of the East Indies, and yields a scent to the perfumer.

TU'BEROUS, in Botany, consisting of roundish fleshy bodies, or tubers; as the roots of artichokes and potatoes.

TU'BULAR BRIDGE, a bridge formed of a great tube or hollow beam, through the centre of which a roadway or railway passes. The first iron bridge of this kind was that designed by Stephenson, for carrying the Chester and Holyhead railway over the Menai Straits. It consists of two rectangular tubes of wrought iron plates, riveted together; one tube being for the accommodation of the up line of rails, and the other for that of the down line. A pier erected upon a rock in the middle of the Straits divides each tube into two spans of 462 feet each, and there is also at each end a smaller tube of 230 feet span to serve as approaches to the bridge. These several tubes are joined together, so as to form one tube for each line of rails, 1524 feet long: and 100 feet above high water. The thickness of the central pier is 45 feet, that of each side pier 32 feet; the tube projects 17 feet 6 inches over the masonry at each end, and rests on rollers, to permit motion, when the tube expands or contracts from change of temperature. This bridge contains 9480 tons of wrought iron, 1988 tons of cast iron, and 1,500,000 cubic feet of masonry. The total expense of its construction was 601,860*l*. It was commenced Aug. 10, 1847, was finished March 5, 1850, and was opened for traffic March 18, 1850. A similar bridge, containing one length of tube, and of a somewhat smaller span, had been previously erected, under Stephenson's direction, over the river Conway, on the same line of railway, and was opened for traffic in 1848. These bridges have, however, been far surpassed by the Victoria tubular bridge over the river St. Laurence, in Eastern Canada. It consists of one tube 6592 feet, or nearly two miles in length: the whole bridge being 9145 feet long. It is 60 feet over the water; has 24 openings, of which the centre one is 332 feet wide, and each of the others 242. The tube is 19 feet high at the centre, 16 feet wide: and contains 9044 tons of wrought iron; with 1,540,000 rivets. Its surface for painting is equal to 32 acres. It is supported on 24 piers; the two central ones being 18 feet wide; and the remaining 22, 15 feet, and altogether with the abutments, containing 2,713,095 cubic feet of masonry. Their strength was required to be enormous; since the ice accumulated during a Canadian winter, on 2000 miles in length, of lakes and mighty rivers, must pass through them, and a large portion of it dash against them. This ice exerts an almost incalculable pressure; and is often piled up to the height of 40 or 50 feet where there is no obstruction—one vast mass sliding up on another. Wooden tubular bridges have long been in use. One was built at Wettingen in 1778, which may be considered as a hollow timber beam: its span was 390 feet. After whole armies, with the artillery, &c., had passed over it in safety, as also a constant traffic for more than 20 years, it, as well as a similar bridge at Schaffhausen, was burned by the French in 1799.

TU'BULOUS, or **TU'BULATED** (*tuba*, a trumpet: *Lat.*), in Botany, having a bell-shaped border; with five reflex segments, rising from a tube: as, a *tubulous* floret.

TU'ESDAY, the third day of the week; answering to the *dies Martis* of the Romans; but dedicated by the Saxons to *Tuisco*.

TU'FA, or **TUFF**, in Geology, a rock composed of small particles of stone, which issued in the shape of dust from a volcano; or as mud, that is, dust mingled with steam. In volcanic countries there are strata of tuffs, some of which had been originally thrown into the sea, and contain marine organic remains; others have been penetrated by water, holding calcareous matter in solution, by which the tufaceous particles have been bound together into a hard mass susceptible of a good polish. Tuffs frequently alternate with beds of basalt and trachyte.

TUFO, in Architecture, a porous, light, calcareous stone, used in the construction of vaults. The '*travertin*' employed in building St. Peter's, at Rome, is of this nature. [See TRAVERTIN.]

TUILERIES (*tuillerie*, a place where tiles are made: *Fr.*), the residence of the French monarchs, on the right bank of the Seine, in Paris. It was begun by Catherine de Medici, wife of Henry II., in 1564, and finished by Henry IV.; but the latest additions were made to it by Napoleon, in 1808. It has been connected by Napoleon III. with the Louvre, forming a splendid pile of buildings. The exterior of the Tuileries is deficient in harmony, having been built at different times, and on very different plans; but the interior is magnificent. It derives its name from having been erected on a place where tiles were anciently manufactured.

TU'LIP (*tulipe: Fr.*), the name of liliaceous plants belonging to the genus *Tulipa* of botanists. They are much cultivated for the regular form and gay colours of their flowers. The tulip has always been a favourite flower with the Belgians and Dutch; and, about a century after its introduction, the mania prevailed to such an extent in those countries, that more than two thousand dollars were often given for a single root.

TU'LIP-TREE, a North American tree belonging to the *Magnolia* order. It is the *Liriodendron tulipiferum* of botanists. The deciduous leaves have a singular shape. The flowers are large and showy, are variegated with different colours, among which yellow predominates; and sometimes resemble those of the tulip. In parts of the United States it constitutes alone very considerable tracts of the forest, and has been found 140 feet high, with a stem 20 feet in circumference. The heart of the wood is of a light yellow colour, and the sap white; the grain is fine and compact; it is easily wrought, polishes well, and is sufficiently strong for purposes requiring great solidity. The tree succeeds very well in England.

TU'MOUR (*tumor*, a swelling: *Lat.*), in Medicine, the morbid enlargement of a particular part; without being caused by inflammation.

TU'MULUS (*Lat.*), a *barrow* or mound of earth in ancient times raised to the memory of the dead. [See BARROW.]

TUN (*tunne: Sax.*), a measure of capacity for liquids. The English tun contains two pipes, or four hogsheads, or 252 gallons.

TUNG'STEN (*tung sten*, heavy stone: *Swed.*), sometimes called Wolframium, a white, hard, and brittle metal, very difficult of fusion; heated to redness, in the open air it burns into the peroxide or tungstic acid. Its spec. grav. is 17·4. It is obtained chiefly from *wolfram*, or tungstate of iron and manganese. Steel is supposed to be greatly improved by the addition of from two to five per cent. of tungsten. Tungstate of soda is employed to render articles of dress uninflammable.

TU'NIC (*tunica: Lat.*), a garment worn within doors by the Romans of both sexes, under the toga; the slaves and common people only appearing in it abroad, in which case it was girded with a belt. The senators wore a tunic with a broad stripe (*clavus*) of purple: the knights had narrow stripes on theirs: and hence the terms *Laticlavii* and *Angusticlavii* applied to persons of these orders. The *Latus clavus* extended from the neck perpendicularly down the centre of the tunic, and, being *woven* in the cloth, it is not represented on statues. The *clavus augustus* consisted of two narrow stripes, also in front of the tunic, and reaching from each shoulder to the bottom; the right of wearing it was permitted also to the children of knights.——*Tunic*, in Anatomy, a coat of membrane.

TU'NICATED (*tunicatus: Lat.*). In Zoology, the term is applied to an order of molluscs, amongst which are the sea-squirts, in consequence of their being protected by an elastic tunic in place of a shell. These are the ascidians of zoologists.——In Botany, an epithet for a bulb composed of numerous concentric coats; as an onion.

TUN'NEL, a subterraneous passage. Some tunnels are cut through hills, to continue the lines of canals, from half a mile to two or three miles long; others are formed on the lines of railroad, where steep hills render them necessary.——The tunnel under the Thames, below London Bridge, was commenced in 1826; and finished for passengers in 1843. It consists of two double archways, each 1300 feet in length; and communicating by openings, cut in the massive centre wall. It cost about 1200*l.* per yard. There have been some enormous tunnels constructed for canal and railway purposes. That on the Thames and Medway Canal, finished in 1800 and now used for the North Kent railway, is 3160 yards in length; and the Box tunnel, on the Great Western Railway, finished in 1838, 3123 yards. But the most enormous undertaking of the kind is that now forming through Mont Cenis, intended to connect France and Italy. It will be 7 $\frac{8}{10}$ miles long, with a width at the base of the arch of 25½ feet, and a height varying from 24½ to 25½ feet. The tunnel has been commenced at each end, and several years must elapse before it is finished, the whole having to be carried through hard rock. Tunnels have been made in very ancient times. The Grotto of Pausilippo, through which the road passes from Baiæ to Naples, is of considerable length, and is probably artificial. Semiramis is said to have made a tunnel under the Euphrates at Babylon more than 3000 years ago.

TUR'BAN (*turband: Pers.*), a head-dress worn by most Oriental nations. It is of very various forms, but generally consists of a piece of fine cloth or linen wound round a cap, which is red or green, roundish on the top, and quilted with cotton. The Turkish sultan wears a turban having three heron's feathers, with many diamonds and other precious stones. The turban of the grand vizier has two heron's feathers; that of other officers, but one.

TUR'BARY, in Law, the right of digging turf on another man's land. *Common of turbary*, is the liberty which a tenant enjoys of digging turf on the lord's waste.

TUR'BINATED (*turbinatus*, conical: *Lat.*), in Botany, shaped like an inverted cone; narrow at the base, and broad at the apex.——In Conchology, wreathed conically from a broad base to a narrow or pointed apex. The top shells afford examples of this form.

TURBINE (*turbo*, a top: *Lat.*—because the machine turns round on a vertical axis something like a *top*), an hydraulic machine, in which the water, having a considerable pressure due to the height of its fall, is allowed to issue through small orifices with a high velocity. The simplest, and probably the oldest form, is what is usually termed *Barker's mill;* it may be described as a vertical tube, having two horizontal tubular arms at its lower extremity; being in the form of an inverted T, and capable of revolving on its vertical axis. There is an aperture near its outer extremity, of each horizontal arm, at opposite sides; or the arms are bent round, so that apertures in the extremities are turned in opposite directions. Another form of turbine has the water flowing from the circumference towards the centre, not as in the preceding form, from the centre to the circumference. When the water flows through the apertures, the parts of the interior immediately opposite to them are acted upon by an *uncounteracted* pressure; which causes a rapid motion in a direction opposite to that towards which the water flows. This rotatory motion of the apparatus is communicated to mill stones, &c. Improved modifications of the turbine, in the shape of *horizontal water-wheels*, are now used. In these, the water is made to traverse curved passages, and by its pressure, while passing through them, it moves the wheel round. They assume a great variety of forms; but will be easily understood, if the principles just alluded to are borne in mind. Turbines are applicable, when the fall of water is too high, and too inconsiderable, for ordinary vertical water-wheels.

TUR'BITH, or TUR'BETH (*turpethus: Mod. Lat.*), a substance used in the materia medica as a cathartic. It is brought from the East Indies, and is the cortical part of the root of a species of convolvulus.——*Turbith mineral*, the yellow precipitate subsulphate of mercury, called *Queen's yellow.*

TUR'BO (*Lat.*), a genus of gasteropodous molluscs, having a regular turbinated shell, with an iridescent interior. The top shells of collectors belong to this genus. They are natives of tropical seas.

TUR'BOT, a large flat fish, the *Rhombus maximus* of ichthyologists, in the family *Pleuronectidæ*. Being a favourite fish for the table, large quantities of turbot are sold in the London market. It grows to the weight of twenty or thirty pounds.

TUR'DUS (a thrush: *Lat.*), in Ornithology, a genus of birds, comprehending the different species of thrush.

TUR'KEY, a name given to gallinaceous birds of the genus *Meleagris*. Our domesticated bird (*M. gallopavo*) is derived from Mexico; but the name Turkey is supposed to have been given to it in the belief that the bird was a native of the country so called. The Honduras turkey (*M. ocellata*) is a much handsomer bird, but is little known in this country.

TUR'MERIC, or INDIAN SAFFRON, the root of the *Curcuma longa*, a plant allied to the Gingers. Externally it is greyish, but internally of a deep bright yellow or saffron colour. Paper stained by it is used as a test in the laboratory; being changed from yellow to brown, by free alkalies, and then carbonates. Turmeric has a slight aromatic smell, and a bitterish taste. It is used for dyeing, and, in some cases, as a medicine; but it is chiefly employed as a seasoning for ragouts and other dishes; and it constitutes a principal ingredient in curry powder. There were 2541 tons of turmeric imported in 1858.

TUR'NERITE, a rare mineral occurring in small crystals of a yellowish brown colour, externally brilliant and translucent. It contains alumina, lime, magnesia, with a small portion of iron and silica.

TURN'ING, in Mechanics, a very ingenious and useful art; in which a great variety of articles are manufactured, by cutting or fashioning them while they revolve upon an axis or line, that generally remains immovable. Every solid substance in nature may be submitted to this process, and accordingly we have articles turned in the metals, in wood, in pottery, in stone, in ivory, &c. The simplest process of turning is that of the potter; who, in the first stage of forming his ware, sticks a piece of soft clay upon a wheel, or flat table, while it revolves horizontally; and in this state of rotation, he fashions it with the greatest facility into vessels of every description. But in most operations of the art the revolving body is cut or shaved by applying a chisel, or other suitable tool, to its surface, while in motion; which requires firmness in the action, or axis of rotation, and also that the tool itself should be steadily supported. The instrument, or apparatus for these purposes, is called a *lathe.* The art of turning is most extensively applicable in all the mechanic arts; for the hardest metals, and the most ponderous articles, as well as the softest wood and the most delicate pivots in a watch, can be fashioned by the turning-lathe.

TUR'NIP, the common name of a cruciferous plant, the *Brossica ropa* of botanists, extensively cultivated for its esculent root. Turnips are a wholesome article of food, much in use. The large rooted varieties have been employed for fodder, during the winter season, from time immemorial. The Swedish turnip has a large root, of a yellowish hue, and is employed for feeding cattle. The plant is the *Brassica campestris*, variety *ruta-baga.*

TURN'PIKES, the name given to the toll gates on the public roads, the ancient gate being a mere pole or pike. The turnpike roads are formed under acts of parliament; and managed by commissioners, trustees, and surveyors. [See ROADS.]

TURN'SOLE, in Botany, a plant of the genus *Heliotropium;* so named because its flower is supposed to turn towards the sun.

TUR'PENTINE (*turpentina: Ital.;* from

terebinthos: Gr.), a transparent resinous substance, procured from different species of the pine and fir. The best sort comes from North America. The method of obtaining it is by making a series of incisions in the bark of the tree, from which the turpentine exudes, and falls down into receptacles prepared to receive it. English turpentine is from the Scotch fir; Venice turpentine, which is more thin and aromatic, is derived from the *pinus larix;* and the common American turpentine comes from the *pinus palustris.* To obtain the *oil of turpentine,* the juice is distilled with water in an apparatus like a common still.

TUR'PENTINE TREE, the *Pistacia lentiscus.* Mastich is obtained from its trunk, by making incisions in it, in the month of August.

TUR'QUOISE, a mineral of a beautiful sky-blue colour; occurring in thin layers, or in rounded masses. It is destitute of lustre, but susceptible of a high polish, and is much used in jewellery; and contrasts well with diamonds and pearls set in gold. It consists chiefly of hydrated alumina; and its colour is probably due to oxides of copper and iron.

TURTLE, the name given to some marine shielded reptiles closely allied to the *tortoise* [which see]. One species, the hawk's bill turtle (*Caretta imbricata*), which lives in the Atlantic and Indian oceans, yields the tortoise shell of commerce. The green turtle (*Chelonia viridis*) found in the tropical parts of the Atlantic, is the animal so much prized by epicures. The head and limbs are but slightly retractile, and the toes are entirely united and enveloped in the common integuments, forming a sort of paddle. Turtles feed on sea-weed at the bottom, but, at a certain season, visit the shore, for the purpose of depositing their eggs in the sand. The instinct which leads the female turtle to the beach to lay her eggs, renders them a prey to man. The fishers wait for them at the beginning of the night, especially when it is moonlight; and, either as they come from the sea, or as they return after laying their eggs, dispatch them by hard blows from a club, or turn them quickly over on their backs, not giving them time either to defend themselves, or to blind their assailants by throwing up the sand with their fins. When very large, it requires the efforts of several men to turn them over, and they must often employ the assistance of handspikes or levers for that purpose. The buckler of this species is so flat, as to render it impossible for the animal to recover the recumbent posture when it is once turned on its back.

TURTLE-DOVE, the *Columba Turtur* of ornithologists, a summer visitor to our islands, where they breed, the parent birds sitting by turns on the eggs. The plaintive *coo* of this bird in the woods is always welcome to the ear.

TUS'CAN ORDER, one of the orders of Architecture; the most ancient, the most massive, and most simple of those invented by the Romans.

TUSSILA'GO (*tussis,* a cough; and *ago,* I act upon · *Lat.*—from its being considered a cure for a cough), in Botany, a genus of composite plants, including the common coltsfoot.

TUS'SIS (*Lat.*), in Medicine, a *cough*, nat. ord *Compositæ.*

TU'TENAG, or *Packfong,* a metallic compound brought from China, called also Chinese copper, or white copper. It consists of copper, zinc, and nickel. Zinc is sometimes called by this name in India.

TUT'TO, or TUT'TI (*Ital.*), in Music, a direction for all to play in full concert.

TUT'TY, the impure oxide of zinc, collected from the chimneys of smelting furnaces.

TWELFHI'NDI, among the Anglo-Saxons, men of the highest rank, who were assessed at 1200 shillings; and, if any injury were done to such persons, satisfaction was to be made according to their worth.

TWELVE TABLES, LAWS OF THE, celebrated laws, framed at Rome by the Decemvirs A.U C 303 They were originally ten, but two more were soon added.

TWI'LIGHT, the faint light diffused through the lower portion of the atmosphere by the reflection of the sun's rays from the higher portion of the atmosphere, after that body has set below, or before it has risen above the horizon. The morning twilight begins, and the evening twilight ends, when the sun is about eighteen degrees below the horizon. At the poles, where there are six months day and six months night, the twilight continues about two months; so that a great part of the half year's night is illuminated.

TYM'PAN (*tumpanon,* a drum: *Gr.*), a part of a printing-press, consisting of a frame covered with parchment; on which the blank sheets are put in order to be laid on the form to be impressed

TYM'PANITIS, or TYM'PANY (same *deriv*), a disease called also *Drum belly;* and consisting in an elastic distension of the abdomen, arising from a morbid collection of gas in the intestines. When caused by air secreted in the abdominal cavity it is generally fatal.

TYM'PANUM (same *deriv.*), in Anatomy, the *drum of the ear;* the membranous partition which separates the auditory passage from the tympanic cavity. This cavity contains the four auditory bones, and it communicates with the open air by means of a narrow canal, called the Eustachian tube.——In Architecture, the triangular space in a pediment enclosed by the cornice of its inclined sides, and the horizontal fillet of the corona; it is often decorated with sculpture.——In Botany, a membrane which sometimes stretches across the mouth of the theca of a moss. It is often styled an epiphragm ——Among the Greeks and Romans, a *tympanum* was a musical instrument, not unlike the tambourine, beaten with the hand.

TYPE (*tupos: Gr.*), in Theology, a sign or symbol; a figure of something to come; as, the paschal lamb was a *type* of Christ. To the word in this sense is opposed *antitype*, Christ, therefore, is the *antitype.*——In Natural History, *Type* is applied to that variety in a species, or species in a genus, or genus in a family, which presents an assemblage of points most characteristic of the species, genus, or family respectively.

TYPE-FOUNDING, the art of manufacturing the metal letters used by printers. The type, or pattern of the letter, is first cut on a steel punch, and then sunk in a matrix of brass or copper, about an inch and a half long, and thick in proportion to the size of the letter it is to contain. The fused type-metal is then poured into the mould, and afterwards loosened from the matrix merely by removing the pressure from the spring A type-foundry is provided with several furnaces, each surmounted with an iron pot containing the type-metal, which usually consists of three parts of lead and one of antimony. The dexterity of the founder is truly surprising; for every movement is executed with such astonishing rapidity and precision, that a skilful workman will cast 500 letters in an hour. The types are then taken by a boy, whose business it is to break off the superfluous metal; and this he does so rapidly as to clear three or four thousand per hour. From his hands the types go to the *rubber*, who sits with a grit-stone slab on a table before him, and having on the fore and middle finger of his right hand a piece of tarred leather, passes each broad side of the type smartly over the stone, so dexterously as to be able to rub 2000 types in an hour The types are now conveyed to a boy, who sets them up in lines in a long shallow frame, with their faces uppermost. This frame, containing a full line, is put into the *dresser's* hands, who polishes them on each side, cuts a groove or channel in the bottom of each, and renders them perfectly symmetrical. Each letter is finally tied up in lines, and a proportionate number of each sort being put together, a *fount of type* is ready for the printing-office.

TY'PHUS (*tuphos*, stupor arising from fever: *Gr.*), in Medicine, a species of continued fever characterized by great debility, a tendency in the fluids to putrefaction, and the ordinary symptoms of fever It chiefly attacks those who have been weakened by any previous debilitating cause, or who are confined in unwholesome and damp situations. It assumes various forms, as low fever, putrid fever, nervous fever, jail fever, &c When nausea and bilious vomiting prevail it constitutes what is termed *bilious fever*. Typhus commences with extraordinary muscular and nervous debility, great depression of spirits, flying pains, sighing, a frequent, small, hard, and fluttering pulse, a foul and brown tongue, impaired taste. As the disease progresses, the debility is increased; the mouth becomes very foul and the breath fetid; the evacuations are extremely offensive and rapidly putrify. The speech then becomes inarticulate muttering, and delirious; there is a tendency to bleeding from the nose, mouth, and bowels; livid spots appear on the surface, hiccup comes on, the hands and feet become cold, and death supervenes. In this climate it may last three weeks or a month: in hot countries eight or ten days. If it does not terminate fatally, the symptoms begin to be favourable about the twelfth or fourteenth day It is contagious, or infectious, and often epidemic.

TYPHOON, the name given to a hurricane, or tornado in the Chinese seas.

TYPOG'RAPHY (*tupos*, a type, and *grapho*, I write: *Gr.*). [See PRINTING.]

TYP'OLITE (*tupos*, an outline; and *lithos*, a stone: *Gr.*), in Natural History, a stone or fossil which has on it impressions or figures of plants and animals.

TY'RANT (*turannos*, literally, a master: *Gr.*), one who exercises arbitrary or excessive power A monarch or other ruler who by injustice or cruel punishment, or the demand of unreasonable services, imposes burdens and hardships on those under his control, which law does not authorize, and which are repugnant to the dictates of humanity ——The word *tyrant*, in its original signification, merely meant an *absolute* ruler; but the frequent abuse of the office led to a different application of the word.

TYRO'SIS (*turos*, cheese: *Gr.*) in Medicine, a disorder in the stomach occasioned by milk coagulating in it.

TYTH'ING (*testha*, the tenth: *Sax*), in Saxon Law, the subdivision of a *Hundred*. It was obliged to produce offenders, or repair the mischief done by them. All free persons above the age of twelve years were bound to belong to some tything. The limits of a tything generally corresponded with those of a parish. It was originally supposed to be a district containing ten freeborn men, of whom each was pledged for the other.

U

U, the twenty-first letter, and the fifth vowel of the alphabet, is generally pronounced nearly like *eu* shortened or blended; as in *annuity*, *enumerate*, *mute*, *infuse*. In some words, as in *bull*, *pull*, *full*, the sound of *u* is that of the Italian *u*, the French *ou*, but shortened. Its other sound is heard in *tun*, *run*, *rub*, &c. Sometimes it is pronounced like a double *o*, as in *rule*, *true*. It is not often used as an abbreviation, but is put for urbis, and thus A U C, anno urbis conditæ (in the year from the building of Rome).

UBIQUITA'RIANS (*ubique*, everywhere: *Lat.*), in Ecclesiastical History, a sect of Lutherans who sprung up in Germany about the year 1540; and maintained that the body of Jesus Christ is (*ubique*) omnipresent, or in every place at the same time, and consequently in the Eucharist.

U'KASE, in Russia, a proclamation, or imperial order published.

UL'CER (*ulcus*: *Lat.*), in Medicine, a purulent solution of continuity, in any of the soft parts of the body, attended with a secretion of pus, or some kind of discharge. Ulcers arise from a variety of causes, and are variously denominated; as *fistulous*, *gangrenous*, *cancerous*, *scrofulous*, *carious*, &c.

ULE'MA, or OULEMA (*Turk.*), a body of learned men, are the administrators of the various powers centred in the person of the Sultan of Turkey, and presided over by the Grand Mufti. It consists of three descriptions of persons; the Imams who are ministers of religion; the Muftis, who are expounders of the law; and the Cadis, who are ministers of justice.

ULMA'CEÆ, in Botany, a nat. order of exogenous trees and shrubs, including, amongst other genera, *Ulmus* (Elm-trees) and *Celtis* (the Nettle trees). The latter bear an edible drupe, sometimes called sugar berry. The flowers of the *ulmaceæ* have no petals, and appear in loose clusters.

UL'MIN (*ulmus*, an elm-tree: *Lat.*), a dark brown substance, which exudes from the bark of the elm, and other trees. It is considered by some as identical with the brown matter of vegetable mould and turf: a substance which greatly contributes to the nutriment of growing plants.

UL'NA (the elbow: *Lat.*), in Anatomy, the larger bone of the fore-arm, reaching from the elbow to the wrist; it is large at its upper extremity, and grows gradually smaller towards the wrist. Its chief use seems to be to support and regulate the motions of the radius.

ULTIMA'TUM (*ultimus*, the last: *Lat.*), in modern diplomacy, the final conditions offered for the settlement of a dispute; or the basis of a treaty between two governments. The word is also used for any final proposition or condition.

UL'TRA (beyond: *Lat.*), a prefix to certain words in modern politics, to denote those members of a party who carry their notions to excess. In 1793, those persons in France were called *ultra-révolutionists*, who demanded much more than the constitution they adopted allowed. When the Bourbons returned to France, in 1815, the words *ultra-royalists* and *ultra-liberals* were much used, and have become common wherever political parties exist.——*Ultra vires* (*Lat.*), a Law phrase applied when a trustee has done something which he was not authorized to do.

ULTRAMARINE (*ultra*, beyond; and *mare*, the sea: *Lat.*), in Painting, a valuable pigment affording a beautiful sky-blue colour.——Its name *ultramarine* is derived from being brought from beyond sea, that is to say, from Hindostan and Persia; and it was originally obtained only from the rare mineral *lapis lazuli*. But excellent ultramarine can now be prepared artificially, with silicate of alumina, silicate of soda, and sulphuret of sodium; its colour being due to the last reacting on the second. Ultramarine was formerly five guineas an ounce; a very good article can now be had wholesale for little more than one shilling a pound. In 1858, 14,562 cwt. of ultramarine, value 77,268*l.* were imported; most probably the greater part of this was artificial.——*Ultramarine ashes*, a pigment which is the residuum of lapis lazuli after the ultramarine has been extracted.

ULTRAMON'TANE (*ultra*, beyond; and *mons*, a mountain: *Lat.*), an epithet applied to countries which lie beyond the mountains: thus France, with regard to Italy, is an ultramontane country.——In Ecclesiastical matters the term is used by writers on this side of the Alps to express doctrines extravagantly favourable to the power and supremacy of the popes, and therefore in accordance with Roman or rather Papal ideas.

UL'VA (*Lat*), in Botany, the *Green Laver*, a plant belonging to the *Algæ*. Three of its species grow in the sea, one in fresh water, and three in damp places on land. The *Ulva thermalis* grows in hot springs at a temperature of 117° Fahr.

UM'BEL (*umbella*, an umbrella: *Lat.*), in Botany, a sort of inflorescence, which consists of a number of flowerstalks or rays spreading from a common centre. It is simple or compound; in the latter, each peduncle bears another series of spreading flowerstalks. Hence *umbellate*, and *umbelliferous*, bearing umbels.

UMBELLIF'ERÆ, in Botany, a large nat. ord. of herbaceous plants (the *Apiaceæ* of some botanists), comprising those which have their flowers in UMBELS. They grow chiefly in the northern parts of the northern hemisphere. The carrot, celery, parsley, parsnip, fennel, coriander, and caraway, belong to this order, which also contains many poisonous plants, such as common hemlock and water hemlock. Others yield matters which are employed in medicine, such as ASSAFŒTIDA, GALBANUM, and OPOPONAX.

UM'BER, in Painting, a pigment affording a fine dark-brown colour. There are two substances used under this name; one, a preparation of the lignite or brown coal, found near Cologne; the other, called *Turkish umber*, an ochraceous iron ore, containing peroxide of iron, peroxide of manganese, silica, alumina, and water. The name is believed to be derived from Umbria, or Spoleto, in Italy, whence it was first brought. It is used in two states; the first, its natural one, with the simple precaution of levigation, or washing; the second, that in which it is found after being burnt. The hues of burnt and unburnt umber greatly differ from each other.——In Ornithology, the *Scopus Umbretta*, a bird belonging to the *Ardeidæ*. It is distinguished from the storks by its compressed bill, whose trenchant column is expanded towards the base; the nostrils are prolonged into a furrow. It inhabits Africa.

UMBILI'CAL (*umbilicus*, the navel: *Lat.*), in Anatomy, an epithet for whatever pertains to the navel; as *umbilical* vessels, *umbilical* region.——In Botany, the *umbilical cord*, or *funiculus*, is the thread which connects the ovule with the placenta. It varies in length in different plants, and is sometimes absent.

UMBIL'ICATE (same *deriv.*), in Conchology, an epithet applied to an univalve shell in which the axis of the column is hollow; such a shell is also styled perforated.——In Botany, an epithet applied to a leaf or other part of a plant which is round, with a depression at the middle.

UM'BO (*Lat.*), the boss or protuberant part of a shield.

UMBO'LDILITE, a Vesuvian mineral, whose primitive form is a right rectangular prism, with a square base. It is of a greenish yellow colour, inclining to brown.

UMB'RIAN, an ancient Italian language spoken to the north of Rome, of which a few fragments of a priestly literature, the tables of Iguvio, have been preserved.

UN, in Philology, a particle giving to words to which it is prefixed a negative signification. *Un* and *in* were formerly used indifferently for this purpose; but the tendency of modern usage is to prefer the use of *in* in some words, where *un* was before used. It is prefixed generally to adjectives and participles, but sometimes also to verbs, as in *unbend*, *unbind*, &c.

U'NA VO'CE (*Lat.*), with one voice; unanimously.

UN'CIAL (*uncia*, the twelfth of a foot: *Lat.*), pertaining to letters of a large size, used in ancient manuscripts.

UN'CIFORM (*uncus*, a hook; and *forma*, a form: *Lat.*), in Anatomy, an epithet for the last bone of the second row of the carpus or wrist; so named from its hook-like process, which projects from the palm of the hand.

UN'CINATE (*uncinatus*, furnished with hooks: *Lat.*), in Botany, hooked at the end.

UNC'TION (*unctio: Lat.*), the anointing with consecrated oil, a practice among the Jews in consecrating kings and priests; also still in use at coronations. One of the seven sacraments of the Roman Catholic church. It is performed in cases of mortal disease, and is called *extreme unction*.

UNDERWRI'TER, one who undersigns a policy of insurance on a ship or its cargo, at a certain rate per cent.

UNDULA'TION (*undulatus*, marked with waves: *Lat.*), a waving motion or vibration; as, the *undulations* of water or air. The undulations of a fluid are propagated in concentric circles.——In Surgery, *undulation* denotes a certain motion of the matter of an abscess when pressed, which indicates its maturity or fitness for opening.

UNDU'LATORY THEORY (same *deriv.*), in Optics, the theory according to which light is transmitted by the undulations of an elastic medium, supposed to pervade the universe. [See LIGHT.]

UN'GUENT (*unguens*, anointing: *Lat.*), in Medicine, a soft composition used as a topical remedy for sores.

UNGUIC'ULATES (*unguis*, a claw: *Lat.*), a primary division of the mammalia, including those which have the digits armed with claws, but free for the exercise of touch on their under surface.——In Botany, an epithet applied to petals which have a broad limb attached by a narrow portion.

UN'GULA (a hoof: *Lat.*), in Geometry, the section of a cylinder, cone, or other solid formed by revolution, cut off by a plane passing obliquely through the base.

UN'GULATES (same *deriv.*), an order of the class mammalia, including those which have the digits inclosed in hoofs, the under surface not being left free for the exercise of touch, such as the ox, the horse, and the elephant.

UNICAP'SULAR (*unus*, one; and *capsula*, a chest: *Lat.*), in Botany, having one capsule to each flower.

U'NICORN (*unicornus;* from *unus*, one; and *cornu*, a horn: *Lat.*), an animal with one horn. According to an examination of the accounts given of the unicorn in ancient and modern times, the opinion of its fabulous character, which has prevailed since the time of Buffon, does not seem to rest on a foundation absolutely certain. Ludovicus Romanus, the traveller, declares that he saw two unicorns alive in the temple of Mecca; some assert that the animal is yet to be found in Thibet, and it is stated by Von Zach that a beast of this description, the male of which has a long and straight horn on the forehead, is found in the district of the ancient Meroe. The animal termed a unicorn, in our version of the Bible, is considered to be the rhinoceros.

UNIFLO'ROUS (*unus*, one; and *flos*, a flower: *Lat.*), in Botany, bearing one flower only.

UNIFORM'ITY, ACT OF (*uniformitas;* from *unus*, one; and *forma*, a form: *Lat.*), the act of parliament by which the form of public prayers, administration of sacraments and other rites, is prescribed to be observed in all the churches. (1 Eliz., and 13 and 14 Car. II.)

UNILA'BIATE (*unus*, one; and *labium*, a lip: *Lat.*), in Botany, having one lip only; as a *unilabiate* corolla.

UNILAT'ERAL (*unus*, one; and *latus*, a side: *Lat.*), in Botany, an epithet for flowers growing only on one side of the common peduncle; as a *unilateral raceme*.

UNILIT'ERAL (*unus*, one; and *literum*, a letter: *Lat.*), consisting only of one letter.

UNILO'CULAR (*unus*, one; and *loculus*, a compartment: *Lat.*), in Botany, seed vessels not separated into cells.——In Conchology, shells not divided into chambers.

U'NION, or ACT OF UNION (*unio*, unity: *Lat.*), in Politics, the act by which Scotland was united to England; or by which the two kingdoms were incorporated into one, in 1706. Also, the legislative union of Great Britain and Ireland, in 1800. The United States of America are also sometimes called the *Union*.——In Architecture, harmony between the colours in the materials of a building.——In Ecclesiastical affairs, the combining or consolidating of two or more churches into one.——Among Painters, a symmetry and agreement between the several parts of a painting.——In Surgery, *union by the first intention* signifies the process by which the opposite surfaces of recent wounds grow together, and unite without suppuration, when they are kept in contact with each other

UNI'SEXUAL (*unus*, one; and *sexus*, sex: *Lat.*), a term applied by botanists to those flowers which have the stamens in one and the pistil in another, instead of having both in the same flower.

U'NISON (*unus*, one; and *sonus*, a sound: *Lat.*), in Music, a coincidence or agreement of sounds; proceeding from an equality in the number of vibrations made in a given time by a sonorous body. Unison consists in sameness of degree, or similarity in respect to gravity or acuteness; and is applicable to any sound, whether of instruments or of the human organs, &c.

U'NIT (*unitas*, oneness: *Lat.*), in Mathematics, any known determinate quantity, by the constant repetition of which, any other quantity of the same kind is measured.

UNITA'RIANS (same *deriv.*), in Ecclesiastical History, a sect who deny the doctrine of the Trinity, and ascribe divinity to God the Father only. *Unitarianism* in England dates almost as far back as the Reformation; and under the names of Arianism and Socinianism, its followers have at times endured much persecution. Unitarians profess to derive their views from Scripture, and to make it the ultimate arbiter in all religious questions; and they assert that, interpreted according to the settled laws of language, the uniform testimony of the sacred writings is, that the Holy Spirit has no personal existence distinct from the Father, and that the Son is also a derived and dependent being.

UNITED BRETHREN. [See MORAVIANS.]

U'NITY (*unitas*: *Lat.*), in Theology, is of two kinds, *unity of faith* and *unity of spirit*. Unity of faith is an equal belief of the same truths of God, and possession of the grace of faith in like form and degree. Unity of spirit is the oneness which subsists between Christ and his saints; by which the same spirit dwells in both; and both have the same disposition and aims.

U'NIVALVE SHELLS (*unus*, one; and *valva*, the leaf of a door: *Lat.*), in Conchology, those of a single piece.

UNIVER'SAL (*universalis*, belonging to the whole: *Lat.*), in Logic, a proposition which has the subject distributed, so that the predicate is declared concerning every thing comprehended in it. It may be either *affirmative* or *negative*. Thus, 'all men are mortal,' or, 'no men are immortal.'

UNIVER'SALISTS (same *deriv.*), a name sometimes given to the *Armenians*, as holding that grace is given to all men, without reserve; and that its operation is universal. On account of holding an opposite opinion, Calvinists are denominated Particularists.

U'NIVERSE (same *deriv.*), the totality of space, and all its material contents and phenomena. Some philosophers suppose it to be filled with an ethereal fluid, in which masses of matter are equally disposed, which masses, like our sun, act as centres of motion, excite luminosity, and transfer motion and momenta to subordinate spheres, like our earth, each centre being millions of millions of miles distant from the others. [See ASTRONOMY, PLANETS, &c.]

UNIVER'SITY (*universitas*: *Lat.*), a name applied to a national establishment for a liberal education, where professors in the several branches of science and polite literature are maintained, and where degrees or honours attached to the attainments of scholars are conferred. Such an establishment is called a *university*, as intended to embrace the *whole* compass of study. The universities of Great Britain are seated at London, Oxford, Cambridge, Durham, St. Andrews, Glasgow, Aberdeen, and Edinburgh. The University of London is of recent foundation, and is composed of University College and King's College. There are two universities in Ireland—that of Dublin or Trinity College, founded by Queen Elizabeth, and the Queen's University, recently established. In their present form, and with their present privileges, they are institutions comparatively modern. They sprang from the convents of regular clergy, or from the chapters of cathedrals in the church of Rome, where young men were educated for holy orders in that dark period when the clergy possessed all the little erudition which was left in Europe. They have long been considered as intended for general purposes; but, as a proof that they had this kind of ecclesiastical origin, it will be sufficient to observe that the pope arrogated to himself the right of vesting them with all their privileges, and that, prior to the Reformation, every university in Europe conferred its degrees in all the faculties by authority derived from a papal bull. The most ancient universities in Europe are those of Oxford, Cambridge, Paris, Salamanca, and Bologna; and in the two English universities the first-founded colleges are those of University, Baliol, and Merton in the former, and St. Peter's in the latter. Oxford and Cambridge, however, were universities, in the original sense of the word, at a very early period, since the former flourished as a seminary of learning in the reign of Alfred the Great, and the latter, if we may credit its historians, at a period still earlier. A university was at first intended merely to supply instruction and confer degrees; the students resided, at their own expense, in halls, &c. Subsequently, colleges were founded by charitable or munificent persons for the entire or partial support of those who were unable to maintain themselves [see COLLEGE]; and finally, when the colleges became the residence also of independent students, the halls were for the most part abandoned. The general arrangements of a British university may be pretty well understood from those of Cambridge. In this university every college is in itself a corporate body, and governed by its own statutes, which must, however, concur with the general laws of the university. Each of the colleges sends deputies both for the executive and legislative branches of the government, and the place of their meeting is termed the senate-house. All the officers of the university, forming the exe cutive part of it, are chosen by the senate, the principal of whom is the chancellor. He is expected to protect and preserve all the rights and privileges of the institution, and to see that strict and impartial justice is administered in every case to the members. The office is entrusted to noblemen of the highest rank. The Vice-chancellor's office is explained by his title; he acts as a magistrate for the university and county, and must be the head of some college. The regents elect two proctors, who are officers of the peace, and superintend the behaviour and discipline of all the pupils. Although there are some particular parts of the duties of these officers which may be considered very unpleasant, yet they must be masters of arts, and are regents by virtue of their office. There are two courts of law in the university of Cambridge, viz. the consistory court of the chancellor, and the consistory court of the commissary. The university sends two members to the imperial parliament of the United Kingdom, who are chosen by the collective body of the senate. A Council, termed the university council, appointed for various purposes, is composed by a *Grace of the senate*, and a solicitor is nominated by the vice-chancellor. The Syndics, chosen from the members of the senate, conduct all special affairs, such as framing laws, regulating fees, and inspecting the library, the printing, buildings, &c. &c. A Degree cannot be conferred without passing a *Grace* for the purpose. All the professors of the sciences are allowed stipends, which are derived from various sources, composed of the university chest, sums from government, or from estates appropriated for that purpose. At the first institution of the university, professorships, or readerships in the different arts and sciences, were established; but these university officers are no longer the main sources of instruction. The several colleges and halls which compose the academical body, have each its own private regulations for the education of its members, but all contribute to the university education. The degrees in Oxford and Cambridge are differently named, or arrived at, in different succession in the different faculties; but degrees in Theology and Medicine can be obtained only after the acquisition of certain degrees in Arts.

UPAS TREE, the *Antiaris toxicaria* of botanists, nat. order *Artocarpaceæ*, a tree rendered famous for its poisonous qualities, which, however, have been very much exaggerated. It was long believed in Europe that there was but a single tree, which was situated in a valley in Java. Its pestilential qualities were said to be so destructive, that neither herb nor animal could live within many miles of its circle, and that none but criminals, few of whom ever lived to return, were sent to gather poison from it. But it is now known to be merely a tree with secretions which contain strychnine, but do not affect the atmosphere around. It is nearly allied to the BREAD FRUIT TREE and the COW TREE. The upas tree has a stem which is cylindrical, perpendicular, and rises completely naked to the height of sixty or seventy, or even eighty feet; near the surface of the ground it spreads obliquely, like many of our forest trees. The bark is whitish, slightly bursting into longitudinal furrows. Near the ground this bark is, in old trees, more than half an inch thick, and, when wounded, yields copiously the milky juice from which the poison is prepared.

UP'LAND, a term for land elevated above the meadows and plains which lie on the banks of rivers, near the sea, or between hills. It is opposed to Meadow, Marsh, Swamp, &c.; and, like Downs, or a gentle hilly country, *uplands* are particularly valuable as affording pasture for sheep.

U'RANITE, in Mineralogy, a phosphate of copper and uranium. It is of a pale gold colour, or yellowish brown; sometimes of an apple-green or emerald hue; and occurs crystallized in rectangular prisms, or in imperfect octahedrons.

URA'NIUM (*ouranos*, the heavens: *Gr.*), a metal discovered in the minerals called pechblende and uranite. It is either a black coherent powder or a white malleable metal, according to the state of aggregation. It is very combustible when exposed to heat, and unites very violently with chlorine and with sulphur.

URANOL'OGY (*ouranos*, the heavens; and *logos*, a discourse: *Gr.*), a discourse or treatise on the heavens; or, in other words, the science of Astronomy.

URA'NUS (*ouranos*, heaven: *Gr.*), the *Georgium Sidus*, or *Herschel*, a planet belonging to our system. Its distance from the sun is 1,800 millions of miles. Its sidereal revolution is performed in about eighty-four Julian years. Its orbit is inclined to the Ecliptic at an angle of only 46′ 28 4. Its diameter is 35,300 miles; its bulk eighty times that of the earth; its density only one-fifth that of our globe. A motion of revolution round its axis has not been made out, but doubtless it exists. Only four satellites have been seen, but possibly there are more. These satellites present the remarkable peculiarities that the planes of their orbits are nearly perpendicular to the ecliptic, and that their orbital motions are retrograde, that is, they move round their primary from east to west.

URARI', OURARI, CURARI, or WOORALY, the Indian names of a virulent poison prepared by the Indians of South America from the wood of the *Strychnos toxifera*; a tree growing in the interior of tropical America. A dart tipped with the poison and blown through a tube of wood, can be made, by the unerring aim of the red man, to take fatal effect on birds and small animals at a distance of fifty or sixty yards. The tree belongs to the same genus as that yielding *nux vomica*, from which strychnine is prepared.

URCE'OLATE (*urceolus*, a little pitcher: *Lat*), in Botany, an epithet for a corolla which is expanded at the middle, but contracted above and below, whilst the limb is small.

UREA (*ouron*, urine: *Gr.*), a crystallizable substance, held in solution in the urine. It consists of carbon, oxygen, and nitrogen

URE'TER (*ourētēr: Gr.*), in Anatomy, the membranous canal which conveys the urine from each kidney to the urinary bladder.

URE'THRA, in Anatomy, a membranous canal or tube which serves as a passage for the discharge of the urine.

U'RIC ACID, in Chemistry, an acid which is always present in human urine and in the excrement of serpents. It constitutes one of the most common forms of urinary calculi, and of the red gravel or sand voided in certain morbid conditions of the urine. Uric acid consists of carbon, oxygen, hydrogen, and nitrogen. Urate of soda is the chief constituent of chalk stones, gouty concretions in the joints, and, when obtained pure, is a snow-white powder.

URIM, a Hebrew word signifying a *luminary*, and hence *fire*. It is connected in its signification with the word *thummim;* both together signify light and perfection. They were precious stones in the high priest's vestments. [See THUMMIM.]

URN (*urna: Lat.*), in Antiquity, a kind of vase of a roundish form, but largest in the middle, destined to receive the ashes of the dead. The substances employed in the construction of these vessels are numerous. Amongst them are gold, bronze, glass, terra cotta, marble, and porphyry. Many urns have been discovered bearing inscriptions; others with the name only of the person whose remains they contained. The Romans derived the form of their urn from the Greeks, who did not, however, use urns as receptacles of the ashes of the dead. It was also customary with the Romans to put the names of those who were to engage at the public games into *urns*, taking them in the order in which they were drawn out. Into such a vessel also they threw the tickets containing their votes at elections. ——The *urna* was also a Roman measure for liquids, containing about three gallons and a half, wine measure. It was half the *amphora*.

UR'SA (*ursus*, the bear: *Lat.*), in Astronomy, the name of two northern constellations; namely, *Ursa Major* and *Ursa Minor*, the Great and Little Bear.

UR'SIDÆ, a family of *feræ*, comprising the bears, racoon, coatimondi, &c.

UR'SULINES, or NUNS OF ST URSULA, a sisterhood founded by Angela of Brescia, in 1537. At first they were not bound to the rules of the monastic life, but devoted themselves merely to the education of children. They were formed into an order by Gregory XIII. in 1577.

URTI'CA MARI'NA (*Sea nettle: Lat.*), an old name for the species of MEDUSÆ, or jelly-fish.

U'SANCE (*Fr.*), in Commerce, the time fixed for the payment of bills of exchange, reckoned either from the day on which the bill is accepted, or from that of its date, varying in different countries, and thus called because wholly dependent on *usage*. The *usance* between London and Paris is one calendar month; hence a bill drawn there on the 2nd of July *at one usance* is, on account of the three days' *grace*, payable in Paris on the 5th of August. A bill is often drawn for a period of *two* or *more usances*.

USE, in Law, originally meant an equitable right to take the rents and profit of land, the ownership of which was vested, through confidence, in another. The system of uses was introduced into this country from the civil law, about the time of Edward III., by the ecclesiastics, who, to avoid the statute of mortmain, caused conveyances to be made, not directly to themselves, but to lay persons as trustees for them. This custom of conveying to trustees soon became very general. It was, however, at once put an end to as far as it regarded religious houses, but has been since regulated, for other purposes, by statute.

USH'ER (*huissier*, a door keeper: *Fr.*), one who has charge of a door.——The *Gentleman Usher of the Black Rod* is an officer of the order of the Garter, who is also an officer of the House of Lords, where he is constantly in attendance. He is chief of the gentlemen ushers who wait in the sovereign's presence chamber. Usher also signifies an assistant to a schoolmaster; where it seems to refer to his office of introducing the scholars to learning.

USTULA'TION (*ustulo*, I scorch: *Lat.*), in Metallurgy, the operation of expelling one substance from another by heat.——In Old Pharmacy, the roasting or torrefying of moist substances over a gentle fire, so as to prepare them for pulverisation.

USUCAP'TION (*usus*, a making use of; and *captio*, a taking: *Lat*), in the Civil Law, the acquisition of the title or right to property by the undisputed possession and enjoyment of it for a certain time prescribed by law

U'SUFRUCT (*usus*, a using; and *fructus*, proceeds: *Lat.*), in the Civil Law, the temporary use or enjoyment of lands or tenements; or the right of receiving the fruits and profits of an inheritance, without diminishing its substance. It is alienable, and therefore differs from *use*, which can be enjoyed only personally.

U'SURY (*usura: Lat.*), a compensation or reward for money lent. In this sense it is merely equivalent to *interest*. In the common business of life, however, it rarely has this signification, but is chiefly used in an odious sense, to express an exorbitant rate of interest. The Jews were not allowed to take interest from one another. The Romans allowed 1 per cent. per month, and punished excessive usury. The amount of legal interest in England was fixed by various statutes, and all contracts made for the payment of a higher interest were absolutely void. But the usury laws have recently been repealed, and now the rate of interest is a free matter of negotiation, except in the case of pawnbrokers. Where interest becomes payable, and no rate has been agreed on, 5 per cent. is the rate allowed by law.

UTILITA'RIANISM (*utilitas*, usefulness: *Lat.*), is the creed which considers utility, or the greatest happiness principle, to be the foundation of morals. 'It holds,' says

Mr. J. S. Mill, who has recently written a little book on the subject, 'that actions are right in proportion as they tend to promote happiness, wrong as they tend to produce the reverse of happiness.'

UTO'PIA, the name of an imaginary island described in the celebrated work of Sir Thomas More (composed in Latin, and published at Louvain, in 1516), in which was found the utmost perfection in laws, politics, and social arrangements. The word is now used to signify a state of ideal perfection.

UTRICULA'RIA (*utriculus*, a *dim.* of *uter*, a bladder: *Lat.*—from the little bladders which often accompany the leaves, and serve to float the plant), in Botany, a genus of plants, nat. ord. *Lentibulariaceæ*. They have been called in English *bladderwort*, having small tuberous roots like the potato.

U'VULA (a *dim.* of *uva: Lat.*), in Anatomy, a soft, round, spongy body suspended from the palate, near the foramina of the nostrils, over the glottis. Its principal use is to break the force of the cold air, and prevent its entering too precipitately into the lungs. When enlarged or relaxed by disease, it is sometimes necessary to amputate a part of it, on account of the obstacle it presents to deglutition, and the tickling cough and retching which it causes.

U'VULA-SPOON, in Surgery, an instrument to be held just under the uvula for the purpose of conveying any substance into the cavity behind.

V

V, the twenty-second letter of the alphabet, is a labial articulation, nearly allied to *f*, being formed by the same organs; but *v* is vocal and *f* is aspirate, and this constitutes the principal difference between them. V has one sound only, as in *vain, very, vote, vanity*. Though *v* and *u* have as distinct uses as any two letters in the alphabet, they were formerly considered as one letter; it was only in the beginning of the sixteenth century that the peculiarity came to be marked. U has since been used as a vowel, and V as a consonant; but in some encyclopædias and dictionaries the absurd practice of arranging together the words which begin with these letters is still continued. As a numeral, V stands for 5; and with a dash over it, for 5000.

VACA'TION (*vacatio*, a being free from duty: *Lat.*), in Law, the period between the end of one term and the beginning of another: and the same in the universities. It also denotes the time when a see or other spiritual dignity is vacant. During the *vacation* of a bishopric the dean and chapter are guardians of the spiritualities.

VACCINA'TION (*vaccinus*, belonging to cows: *Lat.*), in Medicine, inoculation with the cow-pox, intended as a preservative against infection from the small-pox. [See Cow-Pox.]

VACCIN'IUM (*Lat.*), in Botany, a genus of plants, nat. ord. *Vacciniaceæ*. The species are shrubs or trees, as the bilberry, cranberry, &c.

VAC'UUM *Lat.*), in Physics, a space devoid of all matter; and generally conceived by the ancients to exist. The question whether there is such a thing as an absolute *vacuum* in nature or not, has given rise to disputes among philosophers in all ages. The *Torricellian vacuum* is produced by filling a tube, hermetically sealed at one end, with mercury, inverting it into a cup of the same fluid, and allowing it to descend till it is counterbalanced by the pressure of the atmosphere, as in the barometer invented by Torricelli. It is the most perfect vacuum with which we are acquainted. Until recently, modern philosophers believed that the planets moved in an absolute vacuum, but recent observations lead them to doubt that this is the case; for, after the most careful allowance has been made for the attractions of the planets, and the effect of all other known causes of disturbance on Encke's comet, the successive return of that body to its perihelion are accomplished in periods that are constantly diminishing, which is just what would occur if it moved in a medium that offered a small resistance to its motion. It is, however, difficult to reconcile the existence of such a medium with the fact that, during the last 2000 years of observation, no appreciable effect has been produced on the motions of the larger planets. This, however, proves that the resistance, if any, must be feeble, rather than that it does not exist. If there is, in reality, such a medium, a time must inevitably come when all the planets, satellites, and comets will be precipitated into the sun.

VA'DE IN PACE (go in peace: *Lat.*), the words in which sentence of starvation to death, for certain offences, was pronounced in monasteries. The bones of persons who seem to have perished in this way are occasionally found among the ruins of conventual buildings; but Fleury, in his 'Ecclesiastical History,' describes the *vade in pace* as perpetual solitary imprisonment.

VA'DE-MECUM (go with me: *Lat.*), a book or other article which a person constantly carries about with him.

VA'GINATED (*vagina*, a sheath: *Lat.*), in Botany, sheathed; as a stem is sometimes invested by a leaf-stalk.

VAGI'NOPEN'NOUS (*vagina*, a sheath; and *penna*, a wing: *Lat.*), having the wings covered with a hard case or sheath; as *vaginopennous* insects.

VAIR (*varius*, spotted: *Lat.*), in Heraldry, one of the furs employed in blazoning; supposed to represent the skin of a small squirrel.——*Vairy* is the pattern of vair, with more than two colours.——When the bases of figures having this fur in two colours are so ranged as to meet each other, it is called *countervair*.

VALENTINE'S DAY, the 14th of February, a festival in the calendar in honour of St Valentine, who, according to the legend, suffered martyrdom in the reign of the emperor Claudius. There are no circumstances in the life of the saint which seem likely to have given origin to the custom of choosing valentines, or writing to them, as is done about the time of his festival; and it is believed that the practice is one of olden date, substituted for a pagan observance, by which boys and girls drew each other's names on the 15th of February, a day sacred to *Juno Februata*. The reformers attacked the custom, and St. Francis de Sales introduced the drawing of lots for patron saints instead of it.

VALE'RIAN, a plant of the genus *Valeriana*, of which there are many species The root of the *Valeriana officinalis* has an acrid and somewhat bitter taste, and a strong disagreeable odour. It has been long extolled as an efficacious remedy in epilepsy; and is found serviceable in a variety of nervous complaints, but more especially in epileptic and hysterical affections. Cats are exceedingly fond of the smell of its root, so that it is difficult to preserve it in a garden; they seem to be intoxicated by it; and ratcatchers employ its roots to draw the rats together, as they do oil of anise.

VALHAL'LA, or **WALHAL'LA** (the hall of those who died by violence: *Scand.*), the palace of immortality in the Scandinavian mythology, inhabited by the souls of heroes slain in battle. The name is also given to an edifice in the Grecian style, erected by Ludwig I. of Bavaria, near Ratisbon on the Danube, for the purpose of assembling within its walls the busts and statues of all the great men that Germany has produced.

VALO'REM, or **AD VALOREM** (*Lat.*), according to the value; as, an *ad valorem* duty.

VAL'UE (*Fr.;* from *valeo*, I am worth: *Lat.*), in Commerce, the price or worth of any purchasable commodity. The *intrinsic value* denotes the real and effective worth of a thing, and is used chiefly with regard to money, the *nominal* value of which may be raised or lowered at the pleasure of the sovereign; but its real or intrinsic value, depending wholly on its weight and purity, is not at all affected. The value of commodities is regulated principally by the comparative facility of their production, and partly on the relation of the supply and demand. But many other causes operate to raise or depreciate the value of an article; as monopolies, fashion, new inventions, the opening of new markets, or the stoppage of commercial intercourse through war, &c. And, in fact, in all countries where merchants are possessed of large capitals, and where they are left to be guided in the use of them by their own discretion and foresight, the prices of commodities will frequently be very much influenced, not merely by the actual occurrence of changes in the accustomed relation of the supply and demand, but by the mere anticipation of them.——*Value*, in another sense, denotes those properties in a thing which render it useful or estimable, thus, for instance, the *real* value of iron is far greater than that of gold.

VALVE (*valva*, the leaf of a door: *Lat.*), in Anatomy, a membranous partition within the cavity of certain vessels of the body, to afford a passage to fluids in one direction, and prevent their reflux towards the place from whence they came.——In Botany, a capsule or a calyx is said to be valvular when the pieces composing it touch at their edges.——In Hydraulics, Pneumatics, &c., is a kind of lid or cover of a tube or vessel so contrived as to open one way, but which, the more forcibly it is pressed the other way, shuts the closer on the aperture; so that it admits the entrance of a fluid into the tube or vessel, but prevents its return; or admits its escape, but prevents its re-entrance.——*Safety-valve* is a valve in a boiler that opens to allow the escape of steam at a pressure below the strength of the boiler, by which the boiler is prevented from bursting. It is loaded with a weight proportional to the area of its opening, and dependent on the highest pressure which is to be allowed in the boiler. It is sometimes made of a metal, which, if the valve by any accident adheres to its seat [see STEAM-ENGINE], melts and allows the steam to escape, when the pressure, and therefore the temperature, rise beyond a certain point.——*Valves*, in Conchology, the principal pieces of which a shell is composed. They give rise to the distinction into *univalves*, or such as have only one piece; *bivalves*, such as have two pieces; and *multivalves*, such have three or more pieces. [See CONCHOLOGY.]

VAM'PIRE, a blood sucking spectre. A belief in the existence of such beings existed very commonly, in times of superstition, among various nations of Europe. About a century ago, an epidemic dread of Vampires prevailed in Hungary to such an extent as to afford one of the most extraordinary examples of credulity and systematic self-delusion on record.——In Zoology, a species of large bat, the *Vampyrus Spectrum*, a native of South America. It has been asserted that it sucks the blood of animals so as to cause their death; but the truth, says Cuvier, appears to be, that it inflicts only small wounds, which may probably become inflammatory and gangrenous from the influence of the climate. Another South American blood-sucking bat, a species of *Desmodus*, is much dreaded by horses.

VAM'PLET, in Archæology, a piece of steel, formed like a funnel, which was placed on tilting spears just before the hand to secure it, and might be taken off at pleasure.

VANA'DIUM, a metal found in the iron ore of Taberg in Sweden, and in lead ore from Wanlockhead in Scotland. It is white with a metallic lustre, brittle, and difficult to be reduced; is not oxidized by air or water; is not attacked by sulphuric, hydrochloric or hydrofluoric acid; but dissolves in nitric, and nitro-hydrochloric acid, yielding with them solutions of a dark blue colour. Its equivalent is 68·6. The tritoxide of vanadium possesses acid properties and is known as vanadic acid.

VAN'DALS, a ferocious race, who are believed to have come originally from Scandinavia. They seem to have differed only in name from the Goths, whose language they spoke. They settled in the north of Germany, between the Elbe and the Vistula. During the 4th and 5th centuries they became very powerful; and, under Genseric, their king, overran Spain, Gaul, and Italy. They subsequently established themselves in Africa; but were eventually subdued by Belisarius, the celebrated Roman general in the reign of Justinian, who took their king Gelimer, prisoner, and carried him to Constantinople in triumph.

VANE (*vaene: Belg.*), or WEATH'ER-COCK a light body, generally in the form of a thin plate, which is placed on a spindle at the top of a building, and by turning with the wind, points to the part from which it blows.——In ships, a piece of bunting used for the same purpose.

VANIL'LA. This delightful aromatic, so much employed to flavour chocolate and confectionary, is the dried fruit of orchidaceous plants (*Vanilla planifolia*, and other species of the genus), growing in the West Indies, and thence introduced into Java and other hot countries. The fruit is from six to ten inches long, and from a quarter to half an inch broad. It is of a dark brown colour. After being carefully dried (by which operation it is reduced to about one hundredth part of its original weight) it is packed in air-tight metal cases for exportation. In the West Indies the flower is fertilized by means of insects, but elsewhere artificial fertilization must be resorted to.

VA'POUR (*vapor: Lat.*). When liquids and some solids are heated, they are changed into elastic fluids, called *vapours*. Vapours differ from gases or *permanently elastic* fluids, in not retaining their aeriform state at the temperature of the atmosphere. A liquid in the state of vapour is invisible. When cooled, it assumes the liquid state, as mist or fog, and becomes visible. Different substances are changed into vapours, with very different degrees of facility. Fluids are generally more volatile than solids, but there are exceptions; camphor and some other solids evaporate at common temperatures; the fixed oils, sulphuric acid, &c., require a high temperature for evaporation; arsenic and sal ammoniac evaporate without previously assuming the liquid form. Vapours always occupy a greater space than the substances whence they are produced; a cubic inch of water evaporated at an atmospheric pressure of thirty inches of mercury, produces nearly 1700 cubic inches of vapour. Vapours derived from different substances vary in density. Considering the density of atmospheric air as 1000, that of aqueous vapour at the level of the sea, under the ordinary pressure of the atmosphere, will be represented by 625; that of alcohol vapour by 1613; and that of ether by 2586. Hence a vapour such as ether, boiling at a lower temperature than water, would not be an economical substitute for water in the boiler of a steam engine; since a larger quantity must be evaporated to fill the same space of cylinder, and therefore to produce the same amount of motion;—a cubic inch of ether produces only 443 cubic inches of vapour, while a cubic inch of water produces 1696. All pure vapours, for every increase of temperature equal to one degree *Fahr.* increase by the $\frac{1}{480}$th of the bulk they occupy, at 32° *Fahr.* The greater the pressure under which vapour is produced, the higher the temperature required to produce it; and this pressure may be derived, as in the steam boiler, from the pressure of the vapour itself, or the surface of the fluid from which it has risen. At a pressure of only 0·068 inches of mercury, water evaporates at a temperature of 2°; at a pressure of 0·2 inches, it evaporates at a temperature of 32°; at a pressure of 1·98 inches, it evaporates at a temperature of 102°; at a pressure of 30 inches, it evaporates at a temperature of 212°, &c. Equal weights of a given vapour at any temperature contain equal quantities of heat, and are capable of producing the same mechanical effect.

VA'POUR BATH, a contrivance for producing a profuse perspiration by exposing the body to the steam of hot water; the effect being usually increased by friction. The general result of this process is to relax the body, remove obstructions of the skin, alleviate pain and spasmodic contractions, and promote sleep. In the vapour bath, the stimulant power of heat is modified and tempered by the moisture diffused through the air.

VA'RIABLE QUAN'TITIES (*variabilis*, changeable: *Lat.*), in Geometry and Analytics, such as are continually either increasing or diminishing, according to a certain law; in opposition to those which are *constant* and unchangeable.

VARIA'TION (*variatio: Lat.*), in Geography and Navigation, a deviation of the magnetical needle from the true north point; called also *declination*, which are dependent on the earth's motion, and a subordinate electrical action.——In Grammar, change in the termination of nouns and adjectives, constituting what is called case, number, and gender.——*Variation*, in Music, the different manner of playing or singing the same air or tune, by subdividing the notes into several others of less value, or by adding grace, &c.; yet so that the air itself may be discovered through all its embellishments.——*Variation of the moon*, in Astronomy, an inequality in the moon's motion, depending on her angular distance from the sun. It is due to that part of the sun's disturbing force which is at right angles to the radius vectors, and which accelerates the moon, from quadratures to syzygies; but retards it from syzygies to quadratives. It was not observed by the ancient astronomers.

VARICEL'LA (*varicula*, the *dim.* of *varix*, a dilated vein: *Lat.*), in Medicine, the *Chicken-pox*.

VA'RICOSE (*varicosus: Lat.*), in Medicine, an epithet applied to veins of the body that are permanently distended.

VA'RICUS (*Lat.*), in Conchology, ridges on the outside of a shell which indicate the different stages of growth.

VAR'IETY (*varietas: Lat.*), in Natural History, a technical term applied to a race of animals and plants that differ from the type by constant characters. Intermediate links connect the aberrant forms with the normal ones, otherwise the race would take rank as a distinct species.

VARI'OLA (*vario*, I variegate: *Lat.*). [See SMALL-POX.]

VARI'OLITE (*vario*, I variegate: *Lat.*; and *lithos*, a stone: *Gr.*), in Mineralogy, a kind of porphyritic rock, in which the imbedded substances are imperfectly crystallized, or are rounded, giving the stone a spotted appearance. It is an aggregate of felspar and quartz.

VARIO'RUM EDITIONS (*variorum*, of different persons: *Lat.*), in Literature, editions of the Greek and Roman classics, in which the notes of different commentators are inserted.

VA'RIX (*Lat.*), in Medicine, an uneven swelling or dilatation of a vein.

VAR'NISH (*vernis: Fr.*), a fluid which, when spread thinly over a solid surface, forms a coating impervious to air and moisture; and generally gives it a smooth and polished appearance. Varnishes are formed by dissolving substances, which are almost always resinous, in rectified alcohol, or in fixed or volatile oils; thus producing *spirit varnishes*, or *oil varnishes*. The resins most generally used are Turpentine, Copal, Lac, Mastic, Elemi, Sandarach, Amber, Benzoin, Anime, Gamboge, Dragon's blood, Caoutchouc, and Asphaltum.

VARRO'NIAN SATIRE, a species of satire so called from the learned Varro, who first composed it. The style was free and unconfined, containing both prose and verse, intermixed according to the fancy of the writer.

VAS'CULAR (*vasculum*, a small vessel: *Lat.*), pertaining to the vessels of animal or vegetable bodies.——*Vascular System*, in Botany, that portion of the tissue of plants which forms canals serving for the conveyance of fluid and air.

VASE (*vasum: Lat.*), in Architecture, an ornament placed on cornices, socles, or pediments, representing such vessels as the ancients used in sacrifices, &c. The Grecian artists gave to every vase the shape best adapted to its use, and most agreeable to the eye. A great number of these vessels have been preserved to the present day, and offer to artists models of the most beautiful forms. In Etruria and other parts of Italy there have been exhumed many vases which had been in household use. These were distinguished according to their employments by Greek names; thus, vases for holding wine or oil were called *Amphora*, *Pelice*, and *Stamnos*; those for water with three handles, *Hydria* and *Calpis*; those used for mixing wine at a banquet, *Crater*, *Celebe*, and *Oxybaphon*; those for pouring, *Oenochoe*, *Olpe*, *Lecythus*, *Proclius*; those for drinking, *Cantharus*, *Cyathus*, *Cylix*, *Phiala*, *Scyphos*, *Holkion*, *Ceras*, and *Rhyton*; those for unguents, *Alabastra*. Many of these vases are figured in Dennis's Etruria.——Among florists, the calyx of a plant, as the tulip, is called a *vase*.

VA'STUS (large: *Lat.*), in Anatomy, the name of two muscles; namely, the *vastus externus* and *internus*, situated on the outer and inner side of the thigh.

VAT'ICAN, a magnificent palace of modern Rome, built upon the Vatican hill, from which it derives its name. A building on this site was inhabited by Charlemagne in 800. The present pile has been irregularly enlarged, by a long series of popes. It adjoins the church of St. Peter, and is of vast extent, the number of rooms being at least 4,422. It contains a magnificent collection of antiquities, paintings, frescoes, &c., with a noble library, exceedingly rich in manuscripts. The museum of statuary alone is about a mile in length.

VAU'DOIS (*Waldenses: Mod. Lat.*), the inhabitants of certain valleys on the south side of the Alps, from which they derive their name, and who are to be distinguished from those Waldenses who were the followers of Peter Waldo. The Vaudois maintained the purity of their doctrines many ages before the Reformation; and, on account of it, suffered various persecutions; being at one time expelled from their possessions, which, however, they afterwards recovered by force. Their number is, at present, about 30,000.

VAULT (*volta: Ital.*), in Architecture, an arched roof, of which the materials support and sustain each other; it may be circular, elliptical, &c. When its section rises higher than a semicircle, a vault is *surmounted*; when not so high it is *surbased*.

VAV'ASOR, an ancient title of nobility in England; said by Camden to be next below a baron. It was used in France to signify those who held immediately under the higher nobility. In the French romances it meant a poor gentleman.

VEC'TOR (a carrier: *Lat.*), or *radius vector*, in Astronomy, a straight line which is supposed to be drawn from the centre of a planet to the centre of the sun.——In Geometry, a straight line drawn from the focus of a conic section to any point of the curve.

VE'DAS, the sacred writings of the Hindoos, of great antiquity but uncertain date, believed by the Brahmins to have been revealed by Brahma. They are in Sanscrit, and, though forming one work, they are divided into four parts, viz. Rig Veda, Yajur Veda, Sama Veda, and Atharvana Veda. They are regarded as containing the true knowledge of God, of his religion, and his worship. 'Each Veda consists of two parts—the Mantras, consisting of prayers, hymns, and invocations; and the Brahmanas, comprising precepts which inculcate religious duties, maxims explaining these precepts, and theological arguments. They are undoubtedly the most ancient compositions in the whole range of Sanscrit literature. Their obscurity, and the obsolete dialect in which they are written, are such as to render the reading of them difficult even to a Brahmin. The word Vedanta signifies view or object of the Vedas. Under this name there is an ancient work in Sanscrit, said to have been composed 2,000 years ago, and to contain an abstract or quintessence of all the Vedas. The great authority for its doctrine is the collection of sutras or aphorisms.' (Adelung.)

VEDET'TE (*Fr.*), in Military Affairs, a sentinel on horseback, detached from the main body of the army to discover and give notice of the enemy's movements.

VE'GA, a star of the first magnitude in the constellation of the Lyre, the α *Lyræ* of astronomers.

VEG'ETABLE (*vegeto*, I invigorate: *Lat.*) [See BOTANY]. It has been a question much discussed among philosophers in what way plants were originally diffused over the surface of the earth, and three different hypotheses have been invented. Linnæus supposed a single primitive centre of vegetation, whence all species of plants have been gradually dispersed over the globe by winds, rivers, currents, animals, &c. A second hypothesis is, that each species of plants originated in a primitive centre, of which there were several in different parts of the globe, each being the seat of a particular number of species. The third hypothesis is, that, wherever a suitable climate existed, there the vegetable tribes sprang up, and that plants of the same species were, from the first, spread over different regions.——The *vegetable acids* are those acids which are derived from vegetable matters. They are decomposed by a red heat, and nearly all by concentrated hot nitric acid, by which they are converted into carbonic acid and water; but they are less liable to spontaneous decomposition than other substances obtained from plants. The most important are the acetic acid, or vinegar, the oxalic, tartaric, citric, malic, benzoic, and gallic.——*Vegetable alkalies* comprehend those proximate principles of vegetables, which are possessed of alkaline properties. [See ALKALOIDS.]——*Vegetable oils* are divided into fixed and volatile oils, the former of which impart a permanent stain to paper; while the latter, owing to their volatility, produce a stain which disappears by gentle heat. Olive oil and oil of mint are examples of the two.

VE'GETABLE MAR'ROW, the fruit of a plant of the gourd kind, the *Cucurbita ovifera* of botanists, originally growing in Persia, and now cultivated in this and other northern countries. Its flesh is very tender, soft, and of a buttery quality.

VE'HMIC COURTS (*fehm*: *Ger.*), Criminal Courts established in Germany during the middle ages, called also *free courts*; and seemingly derived from those ancient tribunals of the German tribes which were held in the open air. In the 13th century, they became formidable, from being then modelled on a system of secret organization; it is said that 100,000 persons were at one time affiliated to the society. They were bound to attend the secret meetings of the courts when summoned; and to execute their decrees, if necessary, by taking the life of persons condemned. Sometimes these courts had the effect of repressing the lawless violence of the nobility, but they were also liable to be perverted to the gratification of private malice. Various leagues were entered into in the 15th century to put them down, and this was ultimately effected by the introduction of a better system of judicature and police in the various states.

VEIN (*vena*: *Lat.*), in Anatomy, a vessel which receives the blood brought by the arteries, and carries it back to the heart. Veins are continuations of the extreme capillary parts of the arteries, reflected back toward the heart. Uniting their channels, as they approach the heart, all the veins ultimately form three trunks: the *vena cava descendens*, which brings the blood from all the parts above the heart; the *vena cava ascendens*, which brings the blood from all the parts below the heart; and the *vena porta*, or great trunk, which is formed by a union of the veins belonging to the abdominal organs and the organs of digestion, and which, ramifying like an artery in the substance of the liver, transmits its blood by capillaries to the hepatic veins. ——In Botany, the *veins* of plants are an assemblage of tubes, through which the sap is transmitted along the leaves formed of vascular tissue. The term is more properly applied to the finer and more complex ramifications, which interbranch with each other like net work; the larger and more direct assemblages of vessels being called *ribs* and *nerves*.——*Vein*, among miners, a space containing ores, spar, clay, &c.; when it bears ore, it is called a *quick vein*, when no ore, a *dead vein*. Metalliferous veins have been traced in the earth for miles; and many species of stones are also often found in *veins*.

VEL'ITES (*Lat.*), in Antiquity, light armed infantry in the Roman legion, called also *Procubitores*, because employed on outpost duty when the army was before an enemy. They seem not to have been divided into distinct bodies or companies, but to have hovered loosely in front of the army. They were sometimes disposed before the front of the *hastati*; were sometimes dispersed up and down among the void spaces, and sometimes were placed in two bodies in the wings. The *Velites* generally began the combat, skirmishing in flying parties with the first troops of the enemy, and, when repulsed, fell back by the flanks of the army, or rallied again in the rear. Their arms were bows, slings, javelins, a light wooden buckler covered with leather, and a head-piece.

VEL'LUM (*velin*: *Fr.*), a fine kind of parchment made of calves' skin, rendered particularly clear and white. Vellum was used for writing in the time of Eumenes, king of Pergamus. He was anxious to collect a library which should recall that of Alexandria; but, being prevented by the jealousy of the Ptolemies from obtaining a sufficient quantity of papyrus, had recourse to parchment as a substitute. [See PARCHMENT.]

VELO'CIPEDE (*velox*, swift; and *pes*, a foot: *Lat.*), a vehicle consisting of a piece of wood about five feet long, and half a foot wide, resting on two wheels, one behind the other. On this the rider sits, as on horseback, so that his feet touch the ground; while he propels the machine by pressing his feet slightly against the latter, and keeps his balance in the same way. In front of the saddle is a rest for the arms; and the fore wheel may be turned at pleasure, so as to enable the rider to the machine to give any direction he pleases.

VELO'CITY (*velocitas*: *Lat.*), the rapidity with which a body moves, measured by the space traversed in a given time. Velocity is *uniform* when it passes through equal spaces in equal times; otherwise it is *accelerated* or *retarded*. It is *uniformly accelerated* or *retarded*, when the increments or decrements of motion are equal in equal times. Velocity is *absolute* or *relative*; absolute when a body moves over a certain space in a certain time; relative when it has reference to that of another moving body.

VE'NA CA'VA (the hollow vein: *Lat.*). [See VEIN.]

VE'NA POR'TA, or VE'NA PORTA'RUM (the vein of the passages: *Lat.*), produced by the union of the veins of the stomach, intestines, spleen, and pancreas, and ramified in the liver. [See VEIN.]

VENEER'ING, the art of placing a thin piece of a more valuable wood on another which is less expensive in the construction of articles of furniture. Thus mahogany on oak, or deal, or Spanish mahogany on an inferior kind.

VE'NIAL SIN (*venialis*, pardonable: *Lat.*), in Roman Catholic theology, a sin which weakens sanctifying grace, but does not take it away; and which is not necessarily to be mentioned in confession. The reformed churches altogether reject the distinction between mortal and venial sins.

VEN'TIDUCT (*ventus*, the wind; and *ductus*, a conducting: *Lat.*), in Building a passage for wind or air; a subterraneous passage or spiracle for ventilating apartments.

VENTILA'TION (*ventilatio*: *Lat.*), the act of expelling impure air, and of dissipating noxious vapours. Few persons are aware how very necessary a thorough ventilation is to the preservation of health. We can live without food for a considerable time; but keep us without air for a very few minutes, and we cease to exist. It is not, however, enough that we have air; we must have *fresh* air; for the principal by which life is supported is taken from the air during the act of breathing. One-fifth only of the atmosphere is capable of supporting life. By the care we take to shut out the external air from our houses, we prevent the escape of the deteriorated air, and condemn ourselves to breathe, again and again, the same contaminated, unrefreshing atmosphere. Who, that has ever felt the invigorating effects of the morning air, can wonder at the lassitude and disease that follow the continued breathing of the pestiferous atmosphere of crowded or ill-ventilated apartments! It is only necessary to observe the countenances of those who inhabit close rooms and houses, the squalid hue of their skins, their sunken eyes, and their languid movements, to be sensible of the bad effects of shutting out the external air. It is found that an adult spoils four cubic feet of atmospheric air per minute, by respiration; and about three and a half cubic feet, by exhalations from the surface of the body. Hence the air of a close apartment must very soon be seriously vitiated by a number of human beings; particularly if there are also artificial lights, which, by combustion, aid in the mischievous effect produced on the atmosphere. Chemistry has furnished the means of purifying the air of chambers in which persons have been confined with contagious diseases; or in which bad air is generated in other ways, so as to destroy the noxious or offensive power of the effluvia generated in such situations; and thus of preventing its injurious influence. But no fumigation will be of any avail in purifying stagnant air, or air that has been breathed till it has been deprived of its oxygen; such air must be driven out, when its place should be immediately supplied with fresh pure atmosphere. The readiest means of changing the air of an apartment is by lighting a fire in it, and then throwing open the doors and windows; this will set the air in motion, by establishing a current up the chimney.

VEN'TRICLES (*ventriculus*, the *dim.* of *venter*, the belly: *Lat.*), in Anatomy, a word applied to certain small cavities in the body; as, the two cavities of the heart which propel the blood into the arteries to the cavities in different parts of the brain, &c.

VENTRIL'OQUISM (*venter*, the belly; and *loquor*, I speak: *Lat.*), the art of speaking in such a way, that the voice appears to proceed from different places, though the utterer does not change his position, and in many instances does not appear to speak. It has been supposed that sounds were produced by the ventriloquist independently of the labial and lingual organs; but it is certain that practice only is necessary to carry this act of illusion to a high degree of perfection, and that the sound is produced as usual, but with a less opened mouth. The art of the ventriloquist consists merely in this: after drawing a long breath, he breathes it out slowly and gradually, dexterously dividing the air, and diminishing the sound of the voice by the muscles of the larynx and the palate, moving the lips as little as possible; moreover he studies carefully, and thoroughly understands the modifications produced on sound by difference of distance, of position, and other circumstances.

VEN'UE (*vicinia*, neighbourhood: *Lat.*—the place whence the jury are to be taken), in Law, the place where an action is laid, that is, the county in which the cause will be tried. In certain cases the court has power to change the venue.

VENUS (*Lat.*), in Astronomy, a planet of great splendour, known likewise by the names of the *morning* and *evening* star. She is a constant attendant on the sun; and is never seen in the eastern quarter of the heavens when that luminary is in the western quarter. Venus is sixty-eight millions of miles distant from the sun; her sidereal revolution is performed in a little more than 224·7 mean solar days. At the beginning of this century the inclination of her orbit to the ecliptic was 3°, 23′ 28·6″, but it is subject to a slight annual decrease. Her diameter is 7,700 English miles; her volume therefore is 0·927 of that of the earth. Her density is rather more than four-fifths that of the earth. She is supposed to revolve on her axis in about 23h. 21′ 7·2″. Venus has been sometimes observed moving across the sun's disc in the form of a black spot; this is called the transit of Venus. This happened but twice during the last century, viz. in 1761 and 1769, and no other will occur till the year 1874. From the transit of Venus in 1761 was deduced the sun's parallax; and of course his distance from the earth was ascertained with very great accuracy. This being obtained, the distances of the other planets were easily found by observation and calculation.——VENUS, in Malacology, a genus of conchiferous mollusca, of which there are nearly 200 living species. The wampum of the North American Indians consisted of broken shells of *Venus mercenaria* strung on strips of leather, and then used as money.

VENUS DE MED'ICI, a celebrated ancient statue preserved at Florence.

VERAN'DAH, a term of eastern origin applied to a light gallery external to a house, supported on pillars, and often inclosed in front with lattice work. In England verandahs are frequently met in villas and cottage residences, attached to sitting-rooms on the ground-floor, where they afford a good substitute for a colonnade.

VERB (*verbum*, literally, a word: *Lat.*), in Grammar, a part of speech, consisting of an attribute affirmed. Verbs are divided into *transitive*, *intransitive*, and *passive*. A verb substantive expresses mere affirmation, without reference to any property, or attribute.

VER'BAL (*verbalis*, pertaining to verbs: *Lat.*), in Grammar, a word derived from a verb. In English, a verbal is known by the termination *ion*, *ive;* derived from the Latin.

VERBA'TIM ET LITERA'TIM (*Lat.*), word for word, letter for letter.

VERBE'NA, in Botany, a genus of plants, nat. ord. *verbenaceæ*. Their English name is *Vervain*.

VERDE ANTIQUE (*vert antique*, antique green: *Fr.*), in Mineralogy, a mottled aggregate of marble and serpentine. It takes a fine polish, and is used for various ornamental purposes.

VER'DICT (*veredictum*, truly said: *Lat.*), in Law, the answer of a jury given to the court concerning any matter of fact in any case, civil or criminal, committed to their trial and examination. A *special verdict* is one not delivered generally in favour of either plaintiff or defendant, but stating the facts and referring the law arising from them to the judgment of the court, which, in criminal cases, will say whether or not there is a crime in law.

VER'DIGRIS (*vert-de-gris*, the hoary green: *Fr.*), a green pigment, formerly prepared in the south of France by covering copper plates with the refuse of the grapes from which wine had been made. It is manufactured in this country on a large scale by alternating copper plates and woollen cloths previously soaked in pyroligneous acid. It is a mixture of subacetates of copper.

VER'DITER (*verd de terre*, earth green: *Fr.*), a blue pigment, obtained by adding chalk or whiting to a solution of copper in nitric acid. It is a hydrated percarbonate of copper.

VERGET'TE (a small rod: *Fr.*), in Heraldry, a pallet or small pale; hence, a shield divided by such pallets is termed *vergette*.

VER'JUICE (*vergus*: *Fr.*; from *veris jus*, the juice of the productions of spring: *Lat.*), a kind of harsh vinegar made of the expressed juice of the wild apple or crab, which has undergone the vinous fermentation. The French give this name to the sour liquor obtained from unripe grapes.

VER'MES (*Lat.*), in Natural History, the last and lowest class in the Linnæan system. Linnæus comprehends in this class all those living beings which he could not include among the vertebrata or the insecta. The term was limited by Cuvier to what are now known as *annelides* and *entozoa*, and is at present obsolete.

VERMICEL'LI (*Ital.;* from *vermiculus*, a little worm: *Lat.*) A paste made of wheat-flour in the shape of worm-like cylinders of various diameters, the smallest of threadlike being termed *Vermicelli*, and the larger *Macaroni*. It is manufactured by forcing the paste through small apertures in an iron plate, by means of a powerful screw press. It is also cut into ribands and other forms, and is then called Italian paste.

VERMIC'ULAR (*vermiculus*, a little worm: *Lat.*), resembling the tortuous motion of a worm; as the *vermicular* motion of the intestines, called also *peristaltic*.——In Sculpture, *vermicular* or *vermiculated* work; a sort of ornament in Mosaic pavements, winding and representing the tracks of worms.

VER'MIFORM (*vermis*, a worm; and *forma*, a form: *Lat.*), in Anatomy, a term applied to various parts in the human body, bearing some resemblance to worms; as, the *vermiform* process of the cerebellum.

VER'MIFUGE (*vermis*, a worm; and *fugo*, I put to flight: *Lat.*), an anthelmintic medicine; or a substance that destroys or expels worms from animal bodies.

VERMIL'LION (*vermillon*: *Fr.*), a red pigment, of a hue between scarlet and crimson. There are two kinds of vermillion; the one natural or native, and the other common or factitious. *Native vermillion* is found in several quicksilver mines, in the form of a ruddy sand, which only requires to be purified. *Common vermillion* is made of the red sulphuret of mercury; or, as it was formerly called, factitious cinnabar, reduced to a fine powder.

VER'NATION (*verno*, I bloom: *Lat.*), the mode in which the nascent leaves are arranged in a leaf bud.

VER'NIER, an ingenious contrivance, invented by Peter Vernier, for measuring intervals between the divisions of graduated scales, and described by him in 1631. It consists of a small moveble scale, sliding along a graduated scale or arc; and having in a given space a number of divisions greater or less by unity than the number on the same space of the scale or arc. If an inch of the scale or graduated arc is divided into tenths, and ten divisions of the vernier are made equal to an inch and a tenth, each division of the vernier will be equal to one-tenth and one-hundredth of an inch; and any number of divisions of the vernier, equal to a given space to be measured, will be just so many tenths and so many hundredths of an inch; and thus hundredths can be measured by means of a scale divided only into tenths. It would be equally easy to measure thousandths, &c.

VERON'ICA, in Botany, a genus of plants, nat. ord. *Scrophulariaceæ*, containing the speedwell and other wild British plants, as well as some showy garden flowers.

VER'SATILE (*versatilis*; from *verso*, I turn often: *Lat.*), an epithet for that quality which enables persons to turn readily from one thing to another.——In Botany, a *versatile anther*, is one fixed by the middle on the point of the filament, and so poised as to be easily moved.

VERSE (*versus*: *Lat.*), in Poetry, a line, or a part of the composition which contains all the cadences, &c., found in it. The harmony of every verse is complete in itself. Verses are made up of feet, the number and species of which constitute the character of the verse, as *hexameter*, *pentameter*, &c. In the Greek and Roman versification, a foot was determined by its quantity; in the English, quantity is supplied by accent.——*Blank-verse*, poetry in which the lines do not end in rhymes.——*Heroic-verse* that appropriated to epic or heroic poetry; in Greek and Latin, the *hexameter*; in English, &c., the *iambic* of ten syllables, either with or without the additional short syllable; in French, the *iambic* of twelve syllables.——*Versification* is the art of adjusting the syllables, and forming them into harmonious measure. [See POETRY.]

VERST, a Russian measure of length, containing 3,500 feet; about three quarters of an English mile.

VERT (green: *Fr.*), in Heraldry, the colour of green on coats of arms, represented in engravings by lines drawn from the dexter chief to the sinister base.

VER'TEBRÆ (*Lat.*; from *verto*, I turn around: *Lat.*), in Anatomy, the column of bones in the middle line of the bodies of the higher animals, through which the spinal cord passes, and on which the several motions of the trunk are effected. These bones differ considerably in number in the different animals, but in man this column consists of 33 bones, of which 7 called *cervical* are in the neck, 12 called *dorsal* in the back, and 5 called *lumbar* at the loins. Of the remainder 5 are called *sacral* and the lowest 4 *coccygeal*. The cervical vertebræ are smaller than those in the dorsal and lumbar regions; the first one, or that which supports the skull, is called the *atlas*, and the next one is called the *axis*. The dorsal vertebræ decrease in size from the first to the fourth or fifth, and then gradually increase up to the twelfth, which is the largest. To these vertebræ are attached the ribs, which form a bony cage protecting the heart and the great trunks of the vascular system. The lumbar vertebræ are larger than the dorsal. The sacral vertebræ are only separate in the young subject; in the adult they are soldered together, and form but one bone; and the four bones of the coccyx are also soldered together, and constitute the rudiment of a tail, which in many mammalia is largely developed and consists of numerous vertebræ. The vertebræ lock into each other by processes of bone, and between every two there is interposed an elastic cushion of cartilage, which facilitates the motion of the whole. The vertebræ undergo several modifications according to the position; but the elements of a typical vertebræ consist of a bony centrum, around which are disposed four channels formed by *apophyses*, or processes which have received distinctive names; thus those that arise from the posterior part and enclose the spinal cord are called *neurapophyses*. Those arch over and terminate in the neural spine. From each side of the centrum project two transverse processes or *parapophyses*, to which are sometimes attached ribs or *pleurapophyses*; and at the distal extremities of the ribs are the *hæmapophyses*, which are connected with the sternum or breastbone.

VERTEBRA'TA, a subkingdom of animals so named from the possession of a backbone. It is divided into five classes. 1. MAMMALIA, or quadrupeds, of which the females have *mammæ* or teats for suckling their young. 2. AVES, or birds [see ORNITHOLOGY]. 3. REPTILIA, or reptiles. 4. AMPHIBIA. 5. PISCES, or fishes.

VER'TEX (*Lat.*), in Geometry, the top of any line or figure, as the *vertex* of a triangle.——In Anatomy, the crown of the head.——In Astronomy, the zenith, or point of the heavens immediately over the head.

VER'TICAL (from *last*), pertaining to the vertex or zenith. The sun is vertical to the inhabitants within the tropics at certain times every year. A star is said to be vertical when it is in the zenith.——*Vertical anthers*, such as terminate the filaments, and being inserted by their base, stand no less upright than the filaments themselves. *Vertical circle*, in Astronomy, a great circle of the sphere passing through the zenith and nadir, and cutting the horizon at right angles.——*Vertical dial*, a sun-dial drawn on the plane of a vertical circle, or perpendicular to the horizon.——*Vertical leaves*, in Botany, such as stand so erect, that neither of the surfaces can be called the upper or under.——*Vertical line*, in Conics, a right line drawn on the vertical plane, and passing through the vertex of the cone.——*Vertical plane*, in Conics, a plane passing through the vertex of the cone, and parallel to any conic section.——*Vertical plane*, in perspective, a plane perpendicular to the geometrical plane, passing through the eye, and cutting the perspective plane at right angles.——*Vertical point*, that point in the heavens which is over our heads, otherwise called the zenith.

VERTICIL'LATE (*verticillus*, something that turns round: *Lat.*), in Botany, an epithet applied to parts of plants (leaves, flowers, &c.) that are set in whorls, that is circularly round a stem.

VERTI'GO (*Lat*; from *verto*, I turn around), giddiness. It is a common symptom of the fulness of the vessels of the head; and of nervous and general debility. Sometimes it arises from the stomach being overloaded; at others from its being empty. It is a symptom also of various disorders.——In Zoology, a genus of marsh or land snails.

VES'PA (*Lat.*). [See WASP.]

VES'PERS (*vesper*, the evening: *Lat.*), the evening songs or prayers in the Roman Catholic Church.——*Sicilian Vespers*, in French History, a massacre of all the French in Sicily, in the year 1282. It is so called, because the ringing of the bell for vespers was the signal.

VES'TA, in Astronomy, one of the recently discovered ultrazodiacal planets. Its mean distance from the sun is about 224 millions of miles; its sidereal revolution is performed in 1325 7147 mean solar days; its orbit is inclined to the ecliptic at an angle of 7° 8′ 29″; its volume being only about the fifteenth thousandth part of that of the earth, and its surface not larger than the kingdom of Spain. It is the brightest of the smaller planets. [See ASTEROIDS.]

VES'TALS (*vestales*: *Lat.*), in Antiquity, certain virgins consecrated at Rome to the service of the goddess Vesta; and to whom was committed the care of the vestal fire, which was to be kept perpetually burning upon her altar. Their dress was a white vest, with a purple border; a white linen surplice, called *suffibulum linteum*; and over this a large purple mantle, with a long train. On their heads they wore the *infula*, and from the infula hung ribbons. Their period of service was thirty years; during the first ten they were engaged in learning their mysterious duties, during the next ten in performing them, and during the last in teaching them to others. After this was expired they might return to the world, and even enter the marriage state; but few availed themselves of this privilege. They had several privileges; but, when a vestal was convicted of unchastity, she was led to the Campus Sceleratus, and stripped of her habit solemnly by the pontiff. She was then put alive into a pit, with a lighted candle, a little water and milk; and, thus covered up, was left to die.

VES'TIBULE (*vestibulum*: *Lat.*), in Architecture, a porch or entrance into a building.——In Fortification, that space or covered ground which is in front of a guard-house.

VESTIB'ULUM (same *deriv.*), in Anatomy, a round cavity of the internal ear, the opening of which into the cavity of the tympanum is called the *Stapes*; it is connected also with the cochlea and semicircular canals.

VES'TRY (*vestiaire*: *Fr.*; from *vestiarium*, a wardrobe: *Lat.*), a place adjoining the church where the vestments of the minister are kept; also where the parishioners formerly assembled for the discharge of parochial business; whence such a meeting is called a vestry.——*Vestry-clerk*, an officer appointed to attend all vestries, and take account of their proceedings, &c.

VESU'VIAN, in Mineralogy, *Idocrase*, a subspecies of *pyramidical garnet*, a mineral found in the vicinity of Vesuvius and other places. It is generally crystallized in four-sided prisms, the edges of which are truncated, forming prisms of eight, fourteen, or sixteen sides. It is composed of silica, alumina, lime, oxide of iron, and a little oxide of manganese.

VETCH (*vicia*: *Lat.*), leguminous plants, belonging to the genus *vicia*, and extensively cultivated in England under the name of *tares*.

VET'ERINARY ART, or SCIENCE (*veterinarius*, a cattle doctor; from *veterinus*, a beast of burden: *Lat.*), a modern term for what was formerly called farriery. It comprehends a knowledge of the external form as well as the internal structure and economy of the horse; and embraces whatever relates to the diseases to which the horse is liable; with an accurate knowledge of the principles and practice of shoeing, of feeding, exercising, &c. that noble and highly useful animal.

VE'TO (I forbid: *Lat.*), a prohibition, or the right of forbidding, applied to the right of a king or other magistrate or officer to withhold his assent to the enactment of a law, or the passing of a decree.——*Veto* was the important and solemn word which the tribunes or the Roman people made use of when they inhibited any decree of the senate, or law proposed to the people, or any act of other magistrates. The bare pronouncing of the word *veto* was sufficient to suspend the business, without any reasons assigned for their dissent.

VEXIL'LUM (*Lat.*), a flag or standard.——In Botany, the upper petal of a papilionaceous flower.

VI'ADUCT (*via*, a way; *ductus*, a conducting: *Lat.*), any structure, either solid or on arches for the conveyance of a road, and especially of a railway, across a marsh, valley, &c.

VI'A LACTE'A (*Lat.*), in Astronomy, the *Galaxy*, or *Milky way*. [See GALAXY.]

VIAT'ICUM (*Lat.*; from *via*, a journey), among the Romans, an allowance or provision made by the republic for such of its officers or magistrates as travelled upon the business of the state into any of the provinces. The term *viaticum* implies not only money for defraying the expenses of travelling, but their clothes, ornaments, baggage, &c.——*Viaticum*, in the church of Rome, an appellation given to the eucharist, when administered to persons at the point of death.

VIA'TOR (*Lat.*), in Roman Antiquity, an appellation given in common to all officers of any of the magistrates; as lictors, accensi, scribes, criers, &c.

VIBRA'TION (*vibratio*, from *vibro*, I set in tremulous motion: *Lat.*), the regular back and forward motion of a body, such as a pendulum; which being freely suspended swings or vibrates from side to side. The vibrations of the same pendulum are all made in equal times, at least in the same latitude. The word *oscillation* is now generally applied to the slow alternate motion of a pendulous body: the term *vibration* being reserved to express quicker motions, such as those of a sonorous body.——*Vibration*, in Music, the motion of a chord, or the undulation of any body, by which sound is produced. The acuteness and gravity of sound depend on the tension, length, thickness, and density; the number of vibrations in a given time, being directly as the square root of the tension of the cord; inversely, as its length, thickness, or diameter; and inversely as the square root of its density. In rods of the same material the number of vibrations in a given time varies directly as the thickness, and inversely as the square of the length of the vibrating part. If thin elastic plates are set in vibration; for example, by drawing the bow of a violin across their edges, after a small quantity of very fine sand has been strewed over them, the sand will form various figures, and will indicate certain lines of repose, at which there is no motion whatever; rods and strings also break themselves up into distinct vibrating portions separated by points of rest, which may be found experimentally by placing small pieces of paper across the rod or string.

VIC'AR (*vicarius*, a substitute; *Lat.*), the priest of a parish in which the predial or greater tithes are impropriated or appropriated, that is, belong to a chapter or religious house, or to a layman, who receives them.— *Vicar-general*, the bishop's assistant in the general government of his diocese. This title was given by Henry VIII. to the earl of Essex, with power to oversee all the clergy, and regulate all ecclesiastical affairs. In the Church of England, it is the title of an office, which, as well as that of official principal, is united in the chancellor of the diocese. The business of the vicar-general is to exercise jurisdiction over matters purely spiritual.——*Vicars apostolical*, in the Roman Catholic church, those who perform the functions of the pope in churches or provinces committed to their direction, and the functions of bishops in countries where there are not regular dioceses; they are usually of the episcopal order.

VICE (in place of: *Lat.*), a word used in composition, to denote one *qui vicem gerit*, who acts in the place of another, or is second in authority. Thus we say, the *vice-chamberlain*, *vice-chancellor*, *vice-president*, *vice-gerent*, *viceroy*, &c.——*Vice*, in the constructive arts, an instrument used for holding fast any piece of iron, &c., upon which the artificer is working.——Among glaziers, a machine for drawing lead into flat rods for case windows.

VI ET AR'MIS (by force, and arms: *Lat.*), in Law, words made use of in indictments and actions of trespass, to show the violent commission of any trespass or crime.

VIG'IL, in Church affairs, the evening before any feast. The word is derived from the *vigiliæ*, which denoted the night watches among the Roman soldiers; and it was adopted by the first Christians who spent a part of the night preceding the solemn festivals in prayer, to prepare themselves for the coming celebration.

VIL'LEIN (*vilain: Fr.*), a name given, in ancient times, to persons not proprietors of land; many of whom were attached to the soil, and bound to serve the lord of the manor. [See **FEUDAL SYSTEM**].

VIL'LOSE (*villosus*, hairy: *Lat.*), in Natural History, a term applied to anything covered with soft, flexible hairs thickly set.

VIL'LOUS (same *deriv.*), in Anatomy, a term applied to surfaces, such as those of the small intestines which are covered with *villi*, minute folds of the mucous membrane. When injected, villi form interesting microscopic objects, as a network of capillaries are seen.

VINE (*vimea*, a vineyard: *Lat.*), the name of plants belonging to the genus *Vitis*. They are cultivated in most warm and temperate countries; and of which there are an immense number of varieties. In wine countries the vineyards cover large tracts, and the manufacture of wine is an important branch of industry.——In Italy and other southern regions the vines hang from trees, &c. in rich and beautiful festoons. In places more to the north, they are trained to the form of gooseberry bushes. The vine was formerly grown in England, for the manufacture of wine, without any protection, particularly in the more southern counties, having been introduced by the Romans; and we find from the Domesday Book, that abbeys and convents had their vineyards. The inmates of these institutions were many of them foreigners, and they contributed to render the cultivation of the vine tolerably successful. The names of several places in Kent are supposed to be derived from their having been the site of vineyards. In the reign of Henry II., the cultivation of the vine in England began to be neglected. Our intimate connection with France—our actual possession, indeed, of a portion of the wine-growing districts of that country,—contributed to produce this circumstance. But though the making of wine was no longer carried on in so extensive a manner, yet there is sufficient testimony that during the 16th and 17th centuries a considerable quantity of wine was made in England from the produce of the grape. [See **GRAPE**.] That wine has most flavour in which both the skins and stones are bruised and fermented. As a general rule, the varieties of the vine most esteemed for the production of wine have small berries and bunches, with an austere taste. In certain localities, the vine lives only twenty or thirty years; but under favourable circumstances it may last a hundred.——The word *vine* also denotes the long slender stem of any plant that trails on the ground, or climbs and supports itself by winding round a fixed object, or by seizing it with its tendrils or claspers.

VIN'EGAR (*vinaigre*, literally, sour wine: *Fr.*), an impure form of acetic acid obtained from wine, cider, beer, or other liquors, by the acetous fermentation; also from wood, by destructive distillation. The varieties of acetic acids known in commerce are five: 1. wine vinegar; 2. malt vinegar; 3. cider vinegar; 4. sugar vinegar; 5. wood vinegar. In Great Britain vinegar is usually manufactured from malt; though a very considerable quantity, made for family use, is made from cider and British wines. [See FERMENTATION.]

VI'NERY, in Gardening, an erection for supporting vines and exposing them to artificial heat.

VINIFACTEUR (*Fr.*; from *vin*, wine; *facteur*, a factor), an apparatus made use of in France and Spain to improve the spirituous fermentation of wine. During the fermentation, a portion of the etherial parts of the wine escapes from the open vats; and the *vinifacteur* is intended to collect these, and to convey them back to the *must*.

VI'NOUS FERMENTA'TION. [See FERMENTATION.]

VI'OL (*violle: Fr.*), a stringed musical instrument, of the same form as the violin, but larger. Viols are of different kinds; the largest is called the *bass viol*, whose tones are deep, soft, and agreeable.

VIO'LA (*Lat.*), VIOLET, a genus of polypetalous exogens containing numerous species, including those well-known plants, the sweet violet, the dog violet, and the tricolor violet. All the varieties of pansy or heartsease have been produced by cultivation from some of the wild species. The corolla is composed of five unequal petals, of which the inferior is the largest, and is more or less prolonged into a spur at the base. The roots are generally perennial, and, in some species, possess an emetic property, which renders them a useful substitute for ipecacuanha.

VIOLI'NO (*Ital.*; the *violin*), the most perfect of all stringed musical instruments played with the bow. It consists of three chief parts—the neck, the table, and the sound-board. The violin has four catgut strings of different sizes, of which the largest is wound round with wire. The bridge bears them up from the belly, and they reach from one extremity called the tail piece, to the other near the hand, where they are tightened by turning pins. The excellence of the instrument consists in its purity and distinctness, strength, and fulness of tone.

VIOLONCEL'LO (*Ital.*), a musical instrument which comes between the *viola di braccio* (or arm viol) and the double bass, both as to size and tone. It is constructed entirely on the same plan with the violin; but the player holds it between his knees. It generally accompanies the double bass.

VIOLO'NE (*Ital.*), the English *double bass*, a deep-toned musical instrument, the largest of the kind played with a bow, and principally used to sustain the harmony Its strings, which are seldom more than three in number, are an octave below the violoncello.

VI'PER (*vipera*; contracted from *vivipera*, bringing forth alive: *Lat.*), an animal of the snake tribe, the bite of which is more or less venomous in all countries; but in tropical regions it is almost instantly fatal. Under this name are included those serpents which have a broader head than neck, and no pits behind the nostrils. Like many other poisonous groups of serpents, the vipers are ovo-viviparous. The true vipers have the head covered with scales, like those on the back, and very large nostrils. The black and common adders, which belong to this family, are the only indigenous venomous reptiles of Great Britain.

VIR'GINAL, a stringed and keyed instrument resembling the spinnet. It is now quite obsolete, though formerly in great repute.

VIR'GO (the virgin: *Lat.*), in Astronomy, the sixth sign of the zodiac. Being usually represented as a figure with an ear of corn in her hands, it is also called *signum cereris* (the sign of Ceres). The constellation Virgo contains a star of the first magnitude called *spica virginis*.

VIR'TU (*Ital.*), a taste for curiosities connected with the fine arts.

VIR'TUAL FOCUS (*virtus*, efficacy: *Lat.*), the point from which rays, after having been rendered divergent by reflection or refraction, seem to issue.

VIR'TUAL VELOC'ITY (same *deriv.*), in Mechanics, the velocity which any particle of a body in equilibrium would actually acquire during the first instant of its motion, if the equilibrium were from any cause disturbed. Particles which are at different distances from the centre round which a body would revolve, have different virtual velocities proportional to the distance of such particles from that centre.

VIRTUO'SO (*Ital.*), one skilled in antique or natural curiosities; a lover of the liberal arts. The word is now seldom employed.

VI'RUS (*Lat.*), in Medicine, a watery fœtid matter which issues from wounds, and is endued with corrosive and malignant qualities.

VIS (*Lat.*), a word used by the olden writers on physics, to express force. Thus *vis acceleratrix*, accelerating force; *vis inertiæ*, the resistance which a body offers to a change from either motion or rest—so that, when in motion, it will not stop of itself; nor, when at rest, move of itself. Bodies on the surface of the earth *seem* to stop *of themselves*; but their motion is gradually destroyed by friction, and the resistance of the air.——*Vis insita*, that power by which a muscle, when wounded, touched, or irritated, contracts, independently of the will.——*Vis medicatrix naturæ*, a term employed by physicians to express that healing power in an animated body, by which, when diseased, the body is enabled to regain its healthy actions.——*Vis mortua*, that property by which a muscle, after the death of the animal, or a muscle, immediately after having been cut from a living body, contracts.——*Vis nervosa*, a power of the muscles by which they act when excited by the nerves.——*Vis plastica*, that facility of formation which spontaneously operates in animals.——*Vis vitæ*, the natural power of the animal machine in preserving life. The term *Vis* has been often erroneously given to vital operations the result of organization.

VIS'CERA (*Lat.*), the plural of *viscus*, which see.

VI'SCOUNT (*vice comes*, the deputy of a count; *Lat.*), a nobleman next in degree to an earl. The first viscount was created by Henry VI. in 1440.——A *viscount's coronet* has neither leaves nor points raised above the circle, like those of superior degree, but only pearls placed on the circle itself. It is like that of a baron; but has sixteen pearls in place of six.

VIS'CUS (*Lat.*), in medical science, an internal part which has an appropriate use; as the viscera of the abdomen, &c.

VISH'NU, one of the three chief divinities of the Hindoo mythology. He is usually placed second, and his chief attribute is that of preservation. The sects into which his worshippers are divided are very numerous. It is believed that he has appeared on earth nine times, his incarnations being called *avatars*. The tenth has yet to come. His names are innumerable, one of the best known is Krishna, by which he was styled in one of his descents to the earth. Vishnu and Siva are each thought by many of their worshippers to be superior to every other deity, even Brahma. A worshipper of Krishna has put into his mouth the following words—'I am the father of this world: I bear in my hand immortality and death: I am what is and is not: I am the beginning, the middle, and the end of all things: I am Vishnu among the gods, the sun among the stars: I am the essence of all things, and nothing animate or inanimate can exist without me.'

VIS'ION (*visio; Lat.*), in Physiology, the act of perceiving objects by means of the organ of sight. Modern philosophers agree in supposing vision to be produced by rays of light, reflected from the several points of objects, received in at the pupil, refracted and collected in their passage through the coats and humours to the retina, and forming *there* a picture, like that in the *camera obscura*—which very much resembles the eye in principle. The impression thus made is transmitted to the optic nerve, and thence to the brain. [See EYE, OPTICS, &c.]

VISITA'TION (*visitatio: Lat.*), in Ecclesiastical Law, the inspections by a bishop of the different parishes in his diocese, or by an archbishop of the dioceses in his province. Visitations were formerly required to be annual; at present it is the custom at Easter and Michaelmas to summon the clergy to some convenient place. Those for the purpose of confirmation, must be held at least once in three years. Archdeacons have now the care of the parochial institutions, and the duty of examining into whatever relates to churches, parsonages, and parochial visitation by the archdeacons is annual.

VIS'UAL (*visus*, a seeing: *Lat.*), belonging to sight.——*Visual angle*, in optics, that angle under which an object is seen: or that formed at the eye, by rays of light coming from the extremities of the object, and interesting each other, at the centre of the crystalline lens.——*Visual point*, in Perspective, a point in the horizontal line, where it is intersected by the vertical line. [See PERSPECTIVE].——*Visual rays*, lines of light supposed to come from the object to the eye.

VI'TAL FUNC'TIONS (*vitalis*, pertaining to life: *Lat.*), those functions or faculties of the body on which life immediately depends; as the circulation of the blood, respiration, &c.

VI'TIS (*Lat.*), in Botany, a genus of plants, nat. ord. *vitaceæ*. The principal species are the *Vitis vinifera*, the common vine, and the *Vitis Indica*, the Indian vine [See VINE].

VIT'REO-ELEC'TRIC (*vitreus*, pertaining to glass: *Lat.*), in a state of positive electricity, such as is exhibited by rubbing glass.

VIT'REOUS HU'MOUR (same *deriv.*), the pellucid substance which fills the whole bulb of the eye behind the crystalline lens.

VITRIFAC'TION (*vitrum*, glass; and *facio*, I make: *Lat.*), the act, process, or operation of converting into glass by heat; as, the *vitrifaction* of sand, flint, and pebbles, with alkaline salts.

VIT'RIOL (*vitrum*, glass: *Lat.*), from the appearance of its crystals, a term applied by the older chemists to crystallized *sulphate* of *iron* or green vitriol. *Sulphate* of *copper* or blue vitriol, and *sulphate* of *zinc* or white vitriol, obtained these names afterwards. *Oil of Vitriol* is the vulgar name of SULPHURIC ACID.

VITRIOL'IC ACID. [See SULPHURIC ACID.]

VIVA'CE, in Music, an Italian word signifying lively; and *vivacissimo*, very lively.

VI'VARY (*vivarium*; from *vivus*, alive: *Lat.*), a place for keeping living animals, as a park, a warren, a pond, &c.

VI'VA VO'CE (*Lat.*), by word of mouth: as, to vote, or to communicate with another person, *vivâ voce*.

VIVES, in the Veterinary art, a disease of horses and some other animals, seated in the glands, under the ears, where a tumour is formed, which sometimes ends in suppuration.

VIVIP'AROUS (*vivus*, alive; and *pario*, I bring forth: *Lat.*), in Natural History, producing young in a living state; as distinguished from *oviparous*, producing eggs. In its restricted sense, viviparous is applied to that mode of generation, in which the chorion or external tunic of the ovum acquires a vascular adhesion with the uterus: hence only the *placental* mammalia are really viviparous, the rest being *ovo-viviparous*.——In Botany, a *viviparous plant* is one in which either the seeds germinate on the plant, instead of falling, as they usually do, or which produces its living offspring on the leaves or branches.

VIZ'IER, or **GRAND VIZIER** (a porter: *Arab.* applied by a singular metaphor to a high officer of state), the title of the chief minister of the Turkish empire. He is the representative of the sultan, conducts the deliberations of the divan, and decides alone; for by a seal which he receives at the time of his appointment, he is authorized to rule with absolute power, in the name of the sultan. The title of *vizier* is also given to all the pachas of three tails, or pachas of the highest rank.

VO'CAL MU'SIC (*vocalis*, pertaining to the voice: *Lat.*), music produced by the voice, either unaccompanied or accompanied by instruments. Vocal music has many advantages over instrumental, in its endless variety of intonation and expression, and in the support which it derives from its connection with words. [See MUSIC.

VOICE (*voix: Fr.;* from *vox: Lat.*), the sounds produced by the air emitted from the organs of respiration, especially the larynx. The lungs, the wind-pipe, &c., the finely-arched roof of the mouth, and the pliability of the lips, are each of the greatest importance in producing the different intonations which render the human voice so agreeable and harmonious. A good musical voice depends chiefly upon the soundness and power of the organs of utterance and of hearing; and is much promoted by the practice of singing and gymnastic exercises that expand the chest.

VO'LANT (*Fr.*), in Heraldry, an epithet for flying or having the wings spread.

VOL'ATILE (*volatilis*, flying: *Lat.*), in Chemistry, an epithet for substances which evaporate, or gradually pass off, of themselves in the aeriform state: as musk, ammonia, and the various essential oils. Alcohol and ether are called *volatile* liquids for a similar reason, and because they easily pass into the state of vapour on the application of heat.

VOLCA'NO (*Ital.;* from *vulcan*, the God of fire), in Geology, a burning mountain, from which issues from time to time melted matter at a high temperature, ashes, smoke, sulphurous exhalations, &c. When the volcano has long ceased to act, it is said to be *extinct*. Beneath the outer crust of the earth inflammable materials appear to exist, which access of water excites into combustion. It may not unreasonably be supposed that there are within the earth vast masses of potassium, sodium, &c., which on contact with that fluid immediately become converted into matter in a state of intense ignition. There are even chemical substances known, which by mere contact with each other produce the same effect. No doubt hydrogen, which should be evolved in these circumstances, is not a usual accompaniment of volcanic actions; and it is hard also, to conceive that under the influence of such causes, volcanos could continue in activity for the long periods during which some are known to produce these effects. But these difficulties arise, perhaps only from our limited knowledge. Volcanos break forth under the sea, as well as the dry land, and throw up mountains which rise above the level of the water, causing tremblings of the coasts. Their action often extends through five or six hundred miles; and they frequently produce effects which are most frightful and destructive. The subterranean thunder heard at great distances under Vesuvius, prior to an irruption, indicates that there are mighty caverns beneath the earth; and the existence of a subterranean communication between the Solfatara and Vesuvius, is established by the fact that whenever the latter is in an active state, the former is comparatively tranquil. It affords some ground for the conjecture that water is, in some way, an agent in causing volcanic action, that almost all volcanoes of considerable magnitude in the old world are in the vicinity of the sea; and in those where the sea is more distant, as in the volcanoes of South America, the water may be supplied from great subterranean lakes; for Humboldt states that some of them throw up quantities of fish. But the hypothesis of the nucleus of the globe being composed of matter liquified by heat, offers a still more simple and general solution of the phenomena of volcanic fires. Observations made in all countries, in mines and caves, prove that, even at a small depth, the earth's heat is much superior to the temperature of the surrounding atmosphere. A fact so remarkable, and elicited from observations made in almost every part of the globe, connects itself with what we learn of the phenomena of volcanoes. The sinking of mines, Artesian wells, &c., has even furnished us with data, by which we may calculate the rate at which the temperature increases as we descend into the earth. It has been supposed that a crust of only about 200 miles in thickness covers a globular mass of matter, which is in a state of intense ignition, sufficient to fuse with ease the most refractory substances with which we are acquainted. If such be the case, it is easy to conceive that the elastic vapours, which are generated, force to the surface from below the melted matter, and cause it to issue from openings already in existence, or from new ones—if the others are not sufficiently large or near. There are certain regions to which volcanic eruptions, and the movements of great earthquakes, are almost confined; over the whole of vast tracts active volcanic vents are distributed at intervals, and are most commonly arranged in a liniar direction. Throughout the intermediate spaces there is abundant evidence that the subterranean fire is continually at work; for the ground is convulsed, from time to time, by earthquakes; gaseous vapours, especially carbonic acid gas, are disengaged plentifully from the soil; springs often issue at a very high temperature, and their waters are very commonly impregnated with the same mineral matters, which are discharged by volcanoes during eruptions. Of these great regions, that of the Andes is one of the best defined. Commencing southward, at least at Chili, at the forty-sixth degree of south latitude, it proceeds northward, to the twenty-seventh degree, forming an uninterrupted line of volcanoes. The Chilian volcanoes uprise through granitic mountains. Villarica, one of the principal, continues burning without intermission, and is so high that it may be distinguished at the distance of 150 miles. A year never passes in this province without some slight shock; and about once in a century, or oftener, tremendous earthquakes occur, by which the land has been shaken from one extremity to the other, and continuous tracts, together with the bed of the Pacific, have been raised permanently from one to twenty feet above their former level. Hot springs are numerous in this district, and mineral waters of various kinds. Pursuing our course northward, we find in Peru only one active volcano as yet known; but the province is so subject to earthquakes, that scarcely a week passes without a shock; and many of these have been so violent as to create great changes in the surface. Farther north, we find, in the middle of Quito, where the Andes attain their greatest elevation, Tunguragua, Cotopaxi, Antisana, and Pichincha, the three former of which not unfrequently emit flames. From the first of these, a deluge of mud descended in 1797, and filled valleys, 1000 feet wide, to the depth of 100 feet, forming barriers, by which rivers were dammed up, and lakes produced. In the year 1812, violent earthquakes convulsed the valley of the Mississippi at New Madrid, for a space of three hundred miles in length. As this happened exactly at the same time as the great earthquake of Caraccas, it is probable that these two points are parts of one continuous volcanic region: for the whole circumference of the intervening Caribbean sea must be considered as a theatre of earthquakes and volcanoes. On the north lies the island of Jamaica, which, with a tract of the contiguous sea, has often experienced tremendous shocks, and these frequently extend from Jamaica to St. Domingo and Porto Rico. On the south of the same basin, the shores and mountains of Columbia are perpetually convulsed. On the west is the volcanic chain of Guatimala and Mexico, and on the east, the West Indian isles, where in St. Vincent's and Guadaloupe, are active vents. Thus it will be seen that volcanoes and earthquakes occur, uninterruptedly, from Chili to the north of Mexico; and it seems probable, that they will hereafter be found to extend, at least, from Cape Horn to California. In another direction, the volcanic range is prolonged through Borneo, Celebes, Banda, New Guinea, and various parts of the Polynesian archipelago. The Pacific ocean, indeed, seems, in equatorial latitudes, to be one vast theatre of igneous action, and its innumerable archipelagoes, such as the New Hebrides, Friendly islands, and Georgian islands, are all composed either of coralline limestones or volcanic rocks, with active veins here and there interspersed. In the old world, the volcanic region extends from east to west for the distance of about 1000 miles, from the Caspian sea to the Azores, including within its limits the greater part of the Mediterranean and its most prominent peninsulas. From south to north, it reaches from about the thirty-fifth to the forty-fifth degree of latitude. Its northern boundaries are Caucasus, the Black sea, the mountains of Thrace, Transylvania, and Hungary,—the Austrian, Tyrolean, and Swiss Alps,—the Cevennes and Pyrenees, and the mountains which branch off from the Pyrenees westward, to the north side of the Tagus. Respecting the volcanic system of Southern Europe, it may be observed, that there is a central half, where the greatest earthquakes prevail, in which rocks are shattered and cities laid in ruins. On each side of this line of greatest commotion, there are parallel lands of country where the shocks are less violent. At a still greater distance, as in Northern Italy, there are spaces where the shocks are much rarer and more feeble. Beyond these limits, again, all countries are liable to slight tremors at distant intervals of time, when some great crisis of subterranean movement agitates an adjoining volcanic region; but these may be considered as mere vibrations, propagated mechanically through the external crust of the globe, as sounds travel almost to indefinite distances through the air. During the last century, about fifty eruptions are recorded of the five European volcanoes, Vesuvius, Ætna, Volcano, Santorin, and Iceland; but many beneath the sea, in the Grecian archipelago, and near Iceland, may have passed unnoticed. If some of them produced no lava, others poured out torrents of melted matter for months together; so that, however inconsiderable may be the superficial rocks, which the operations of fire produce on the surface, when it is computed that on the whole globe 2000 volcanic eruptions occur in the course of a century, we must suppose the subterranean changes now constantly in progress to be on the grandest scale. [See EARTHQUAKE.]

VOL'TA, in Music, an Italian word, signifying that the part is to be repeated, one, two, or more times. Thus *Si replica una volta*, means that the piece is to be performed *over again*.

VOLTA'IC ENGRA'VING. [See ELECTROTYPE, and ENGRAVING.]

VOL'TAISM, or VOLTAIC ELECTRICITY (from *Volta*, who made some of the earliest discoveries regarding it), the phenomena arising from the development of electricity, by means of chemical action and the use of the *voltaic* battery. [See GALVANISM.]

VOLTAM'ETER, an instrument for measuring the intensity, &c., of an electric current.

VOL'UME (*volumen*, from *volvo*, I roll: *Lat.*), a roll or book; so called because the ancient books were rolls of bark or parchment. This manner of arranging books lasted till Cicero's time. The several sheets or pieces were glued or pasted end to end, and written only on one side. At the bottom a stick was fastened, called *umbilicus*, round which it was rolled; and at the other end was a piece of parchment, on which the title of the book was written, often in letters of gold.

VOL'UNTARY (*voluntarius*, of one's own free will: *Lat.*), in Music, a piece played by a musician extemporarily, according to his fancy.

VOL'UNTEER (*volontaire*; from *same*), a person who enters into military or other service of his own accord.

VOLU'TA (*voluto*, I twist: *Lat.*), in Natural History, a genus of testaceous gasteropodous molluscs, chiefly found in the tropical seas. Their shells are often of great beauty, and sometimes of great size. To this genus belong the admiral shells, tiger shells, &c.

VOLU'TE (*volutus*: *Lat.*), in Architecture, a kind of spiral scroll, formed at each side of an Ionic capital. It is used also in Corinthian and composite orders, but is then of a smaller size, and placed diagonally. In the Corinthian the volutes are more numerous, but smaller than in the composite.

VOMITO'RIA (*Lat.*; from *vomo*, I pour forth), the openings or gates in ancient theatres and amphitheatres, by which the spectators entered and left.

VOR'TEX (*Lat.*; from *verto*, I turn around), a *whirlpool*, formed by the water running rapidly round; there is a cavity in the middle, into which floating bodies are drawn. The word is also applied to a *whirlwind*. In the philosophy of Des Cartes, a *vortex* means a collection of material particles, forming a fluid or ether, and having a rapid rotatory motion round an axis. He endeavoured, by means of this hypothesis, to explain the motions of the heavenly bodies; but it is inapplicable to those which, like the comets, traverse the heavens in all directions. His object was to show that the universe might assume, and preserve its present form, on mechanical principles.

VOTE (*votum*, a wish: *Lat.*), the suffrage or resolve of each of the members of an assembly, where any affair is to be carried by a majority; but more particularly the resolves of any members of either house of parliament.

VOUSSOIRS (*Fr.*), the stones which immediately form the arch of a bridge; their joints should be perpendicular to the curve of the intrados.

VOW (*vœu*: *Fr.*; from *votum*: *Lat.*), a solemn and religious promise, or oath. [See OATH.] The use of vows is found in most religions. They make up a considerable part of the pagan worship, being made either in consequence of some deliverance, under some pressing necessity, or for the success of some enterprise. Among the Jews, all vows were to be voluntary, and made by persons wholly in their own power; and if such person made a vow in anything lawful and possible, he was obliged to fulfil it. Among the Roman Catholics, a person is constituted a religious by taking three vows, that of poverty, chastity, and obedience.——*Vows*, among the Romans, signified sacrifices, offerings, presents, and prayers made for the Cæsars and emperors; particularly for their prosperity, and the continuance of their empire.

VOWEL (*voyelle*: *Fr.*), a letter which does not require the aid of another, for its pronunciation.

VULCAN'IC THEORY (*vulcamus*, fire: *Lat.*), a system which ascribes the changes on the earth's surface to fire; while another, called the *Neptunian*, ascribes the whole to water.

VUL'GATE (*vulgatus*, commonly known: *Lat.*), a very ancient Latin translation of the Bible, which was made from the Greek of the Septuagint. It is the only one acknowledged by Roman Catholics to be authentic.

VUL'PINITE, in Mineralogy, an anhydrous sulphate of lime, containing a little silica. It is found at Vulpino in Italy, and is used by Italian artists for small statues, and other ornamental work, under the name of *marono bardiglio*.

VUL'TURE (*vultur*: *Lat.*), the name of some diurnal accipitrine birds, having an elongated beak, curved only at the extremity, with more or less of the head, and sometimes of the neck, denuded of feathers. The wings being very long are, in walking, curved in a half distended state. The birds are rapacious to an extreme degree, and sometimes feed in the midst of cities unterrified. In India, they are of so much service in chasing away the carcases of animals, that they are unmolested. They prefer food that is tainted to that which is fresh; they are found most numerous in warm climates, and must be regarded as a race of creatures eminently useful in clearing the surface of the globe from putrid remains, which would otherwise infect the air, and produce pestilence. The Egyptian vulture has been sometimes seen in England. Another species, the *Vultur fulvus* or Griffon Vulture, is an inhabitant of Continental Europe as well as the Lammergeyer, *V. cinereus*. Some tropical species are known to seize tortoises, carry them into the air, and then let them drop to the earth, repeating this process until they are killed. The condor of South America is closely allied to the vultures.

W

W, the twenty-third letter of the English alphabet, takes its written form from the union of two V's, and its name of *double u*, from the Roman capital V representing that which we call U. In English it is always followed either by a vowel, or by *h*, as in *when*; or by *r*, as in *wrong*. The *w*, being a strong breathing, is nearly related to all aspirated sounds, and through them again to the gutterals, so that we find *w* and *g* often interchanged in different languages, as in the words *William*, *Guillaume*, &c. In German, *w* is pronounced like an English *v*, *v* having the sound of an *f*. When *w* commences a syllable it is a consonant; in other cases it is a vowel.

WACK'E (*Germ.*), in Geology, an earthy variety of trap with an argillaceous appearance, and resembling hardened clay. Its colours are greenish-grey, brown, and black.

WAD, or **WAD'DING**, a stopple of paper, tow, old rope-yarn, &c. forced into a gun to keep in the powder and shot.

WADD, in Mineralogy, *plumbago* or black lead. Black wadd is an ore of manganese found in Derbyshire, and of four kinds: the fibrous, ochrey, pulverulent, and dendritic.

WAD'SETT, an ancient tenure or lease of land in the Highlands of Scotland. It is a mortgage; and when the mortgagor pays the public burdens, is a *wadset improper*: but when the wadsettee pays them, is a *wadset proper*.

WA'GER (*gages*: *Fr.*), anything pledged on chance. Wagers are valid in law unless rendered expressly void by statute or such as have an immoral tendency. A wager on horse racing was invalid if for more than 10*l.*; but it is now recoverable. Wagers on merely speculative subjects, arising out of circumstances in which the parties have no interest, cannot be recovered; when a wager is illegal, the parties may recover their deposits from the stakeholder.

WA'GER OF BAT'TLE, or **BAT'TEL**, an ancient mode of trial by simple combat, where, in military, civil, or criminal cases, the defendant might fight with the plaintiff to prove the justice of his cause. This relic of barbarism and injustice has been only recently abolished. It was also used in affairs of chivalry and honour.

WA'GER OF LAW, a proceeding in which the defendant in an action of debt by simple contract, took an oath in court in the presence of eleven compurgators, who swore they believed him, that he owed the plaintiff nothing, on which the law allowed him his discharge. This mode of proceeding has been abolished.

WA'GES, the compensation paid to those employed to perform any kind of labour or service; the term is, however, usually confined to the sums paid to artisans, labourers, and servants. Wages are modified by the agreeableness or disagreeableness of the employment; the ease and cheapness, or difficulty and expense, of learning it; its constancy or inconstancy; the great or little trust it supposes; the probability or improbability of success in adopting it. The rate of wages is necessarily liable to great variation; it will naturally increase if the capital to be expended on manufactures, &c., increase to a greater extent than the population; and it will diminish in opposite circumstances; but it never can remain long below what will be sufficient for the sustenance of the labourers, &c., and their families; the rate at which they can support themselves having, in all cases, a serious effect on that of the wages they receive. [See LABOUR].

WAG'TAIL, the name of some small birds belonging to the genus *Motacilla* of ornithologists. They have long tails, to which they give a graceful fanning motion. There are five species in this country.

WAHA'BEES, a fanatical Mohammedan sect which appeared in Arabia at the beginning of the last century under the leadership of Abdul Wahal. They accepted the Koran, but rejected the marginal annotations and the traditionary law. Mahomet was regarded as a mortal man honoured by a divine mission, but they held that to worship at his tomb savoured of idolatry, and they thought it would be right to destroy the sepulchres of saints throughout Arabia and Persia. In many other respects they disagreed with the popular creed, and they attempted to carry out their own views by force. They took possession of Mecca and Medina. Mohammed Ali, the Pasha of Egypt, sent troops against them, but it was only after several bloody contests that they were got under. Some remains of the sect, however, still exist.

WAIFS (*waflan*, to abandon: *Sax.*), in Law, goods found, of which the owner is not known, and which are claimed by the crown or lord of the manor. These were originally such goods as a thief, when pursued, threw away to prevent his being apprehended; but the owner, on complying with certain conditions within a year and a day, was entitled to restitution.

WAIST (*wast*: *Belg.*), in a ship, that part which is between the quarter-deck and forecastle; but in ships where there is no quarter-deck, the waist is the middle part of the ship.——The small part of the body between the breast and hips.

WA'ISTCLOTHS, coverings of canvas or tarpaulings for the hammocks, stowed on the gangways, between the quarter-deck and forecastle.

WAITS, itinerant musicians who played in the streets on the nights of Christmas holidays.

WA'IVER, in Law, the passing by, or declining to accept a thing; applied either to an estate, to a plea, &c. In some cases, where an action of tort and an action of contract both lie, the aggrieved party declines the former, and pursues the latter remedy; this is *waiver of tort.*

WA'IWODE, in the Turkish empire, the governor of a small province or town.

WAKE (*wacian*, to watch: *Sax.*), a *vigil:* the feast of the dedication of the church, formerly kept by watching all night. At present fast days are usually called *wakes* by the English peasantry. The wake was formerly held on the Sunday after the day of the dedication, or more usually on the festival of the saint to which the church was dedicated. In Ireland, this is called the *patron* day, and by the word wake is understood there the observances used by the lower orders in watching a dead body during one or two nights before interment; candles being lighted around it, and the watchers being supplied with tobacco, whiskey, &c.; such wakes were formerly at least but too often scenes of disorder and excess.——The *wake of a ship* is the track it leaves in the water. By her *wake* the sailors are enabled to judge what way the ship makes. If the wake be right astern, they conclude she makes her way forwards; but if it be to leeward a point or two, then they conclude she falls to the leeward of her course. When one ship, giving chase to another, is got as far into the wind, and sails directly after her, they say, she has got into *into her wake.*

WAL'DENSES, in Ecclesiastical History, a sect which derived its name from Peter Waldo, a merchant of Lyons, who preached his peculiar doctrine about the year 1180. They have been confounded with the Vaudois, who existed before them; and with the Albigenses to whom Manichæan tenets have been, though without sufficient authority, imputed. They are believed to have rejected an established succession in the priesthood and the Roman Catholic doctrine of the sacraments; also to have protested against the ecclesiastical abuses of the time, as well as against oaths, lawsuits, warfare, and the accumulation of wealth.

WALES OF A SHIP, an assemblage of strong planks, extending along a ship's sides, throughout the whole length, at different heights; and serving to strengthen the decks and form the curves. They are distinguished into the *main wale* and the *channel wale.*

WALL'-CRESS, the common name of plants belonging to the genus *Arabis*, nat. ord. *Cruciferæ.*

WALL'-EYE, the *Glaucoma*, a disease in the crystalline humour of the eye.——In horses, an eye in which the iris is of a very light gray colour.

WALL'-FLOWER, a hardy evergreen plant of the genus *Cheiranthus*, which, in the wild state, grows in the clefts of rocks and old walls; producing a fine golden-yellow flower, strongly and agreeably scented. When cultivated, it is a beautiful and favourite ornamental plant, the flowers being of various shades, large, and brilliant. There are many species.

WALL'-KNOT, in the Marine, a particular sort of large knot raised upon the end of a rope by untwisting the strands and interweaving them against each other.

WALL PLATE, in Architecture, a piece of timber placed on a wall for girders, joists, and other timbers to rest upon.

WAL'NUT, the fruit of a well-known deciduous tree, the *Juglans regia*, of which the native country is Persia. Previously to the very general introduction of mahogany, the wood of the walnut-tree was extensively used by cabinet-makers and turners; and it is considered superior to every other sort of wood for the mounting of guns. In N. America there are several other species of *Juglans*, of which the Black Walnut (*J. nigra*) and the Butter nut (*J. cinerea*) are the most useful.

WAL'RUS, in Zoology, the *Morse* or sea-horse. [See MORSE.]

WALTZ (*walzen: Germ.*), a national German dance, but now common in England, and other European countries. It is said to have originated in Bohemia.

WAM'PUM, sea-worn fragments of the *Venus mercenaria*, or bivalve shell, used by the American Indians as money or a medium of commerce. These shells are run on a string, and form a broad belt, which is worn as an ornament or girdle.

WANDEROO', in Zoology, a monkey of Ceylon and Malabar. The other monkeys are said to pay it a profound respect; and its appearance is certainly grave and venerable; but it does not seem endowed in any special way.

WAN'LASS, or *driving the wanlass*, an old Law term for driving deer to a stand, that the lord may have a shoot; an ancient customary tenure of lands.

WAP'ENTAKE (weapon take), in Law, a division or district, peculiar to some of the northern counties of England; and answering to the *hundred*, or *cantred*, in other counties. Yorkshire is subdivided into wapentakes. This name had its origin in a custom of touching lances or spears, when the chief or leading man of the hundred entered on his office.

WAPITI DEER, the Red Deer of the Canadians, the *Cervus Canadensis* of zoologists. It is a large but stupid animal, and its flesh is of inferior quality. The male carries five antlers, which are shed annually.

WAR (*wær: Sax.*), a contest between nations or states, carried on by force; either for defence, for redressing wrongs, for the extension of commerce or acquisition of territory, or for obtaining and establishing the superiority and dominion of one over the other. When war is commenced by attacking a nation in peace, it is called an *offensive* war, and such attack is *aggressive.* When war is undertaken to repel invasion or the attacks of an enemy, it is called *defensive;* and such a war is not only justifiable, but laudable.——*Civil War*, a state of internal hostility, in which opposite parties of the same nation contend for the mastery by force of arms.——*Holy War*, a term given to a crusade undertaken for the purpose of delivering the Holy Land, or Judæa, from infidels. These *holy* wars were carried on by most *unholy* means.——*Declaration of*

War. Formal declarations of war, by Heralds, are now out of use; there is at present merely a *Manifesto* [which see]; and the permission of *reprisals* is usually the step which precedes actual hostilities. By the law of nations, enemies who have not been taken in arms, or who have submitted, are not to be put to death; neither are prisoners, except in very extreme cases. Acts of hostility are lawful only when committed by the express or implied command of the state; hence bands of marauders may be treated as banditti, and private citizens taking up arms are liable to be considered as such. The property belonging to the government of a vanquished nation belongs to the victors; but not that of private individuals, unless found at sea. It has been the custom of Great Britain to seize and condemn as droits of Admiralty the property of an enemy found in our ports at the commencement of hostilities.

WARD (*weardian*, to guard: *Sax*), in Law, the heir of the king's tenant *in capite*, during his nonage; whence the term has since been applied to all infants under the power of guardians; or such as are under the control and protection of the lord chancellor, who are called *wards in chancery*.——A certain district, division, or quarter of a town or city, committed to an alderman. There are twenty-six *wards* in London.

WAR'DEN (same *deriv.*), a keeper; as, the warden of a prison, &c.——*Warden of a college*, the head or president.——*Lord Warden of the Cinque Ports* The constable of Dover Castle was appointed to this office, and was made guardian of the adjacent coast by William the Conqueror. The lord warden has the authority of admiral in the Cinque Ports, and their dependencies. He formerly had power to hold a court of admiralty, and courts of law and equity. He was the returning officer of all the ports, and his salary was 3000*l*. per annum. [See CINQUE PORTS]——There is also a *Lord Warden of the Stannaries* [See STANNARIES]

WARD'MOTE, a court kept in every ward in London, usually called the *wardmote court* It has power every year to inquire into all deficiencies with regard to the officers of the ward, to prevent disorders, gaming, &c.

WARD'-ROOM, a room in a ship of the line, appropriated to the principal officers; in frigates it is called the *gun-room.*

WARP (*wearp: Sax*), in Weaving, the threads which are extended lengthwise in the loom, and crossed by the woof.——In Nautical affairs, a rope or towing line, employed in drawing, towing, or removing a boat or vessel.——In Agriculture, a slimy substance deposited on land by rivers liable to overflow; the mud they contain is deposited sometimes to the depth of one or two inches, and contributes greatly to the fertility of the soil; *warping* has been practised on the banks of the Po, and other rivers in the north of Italy, from the earliest times.

WAR'RANT (*guarantir*, to warrant: *Fr.*), in Law, a precept, under hand and seal, authorizing an officer to seize an offender, and bring him to justice.——*Warrant of attorney*, an authority given by a person to an attorney to appear and plead for him; or in a more general sense, that by which a man appoints another to act in his name, and warrants his transaction.——*Search warrant*, a precept authorizing a person to enter houses, &c., to search for stolen or contraband goods, or to discover whether a criminal be there concealed——*Warrant officer* an officer holding a warrant from the navy board; the gunner, boatswain, and carpenter are warrant officers.——*Press warrant*, in the navy, a warrant issued by the admiralty, authorizing an officer to impress seamen

WAR'RANTY (same *deriv.*), in Law, a promise or covenant, by which a purchaser may have satisfaction from a seller, if he sells what is not his own, or that for which he has not a sufficient title. Warranty of real property is obsolete; and, with regard to things personal, no express warranty is now required that the buyer may have satisfaction if the title of the seller was deficient The seller is not obliged to answer for the goodness of an article, unless at the time of sale he has warranted it to be good; or unless he has in any way misrepresented it. Every affirmation made by the vendor, at the time of sale in relation to the goods, amounts to a warranty.

WAR'REN (*garenne: Fr.*; from *wahren*, to protect: *Teuton.*), a franchise or privileged place for keeping beasts and fowls of the warren; hares, partridges, pheasants, and rabbits, to which some had quails, woodcocks, waterfowl, &c. In common language, a *warren* is a surface of poor sandy soil, on which rabbits are kept.

WASH, the fermented liquor, from which spirit is distilled.

WASP (*wæsp: Sax*; from *vespa: Lat*), a genus of hymenopterous insects, the female and neuter of which have powerful and venomous stings. The nests of wasps are highly curious structures, divided into cells, with walls made of vegetable substances, and as they do not lay up honey like bees, they die, or are torpid in the winter. The *hornet* is larger than the common wasp, and forms its nest in holes or roots of trees, but both are equally voracious.

WAS'SAIL-BOWL, a large drinking vessel, in which the Saxons, at their public entertainments, drank health to each other, saying, 'Wæs hæl!'—'Health be to you!' or 'Your health!' It was also a Saxon custom, to go about with such a bowl, at the time of the Epiphany, singing a festival song, drinking the health of the inhabitants, and, of course, collecting money to replenish the bowl. This custom, from which christmas-boxes, christmas-ale, bellmen's verses, and carols, are all, probably, more or less derived, was called *wassailing;* and those who practised it *wassailers.* In some parts of the kingdom, the primitive custom, and its name, are still retained.

WASTE (*Teut.*), in Law, the destruction, or removal of, or injury to something, forming an essential part of an inheritance; as houses, timber, &c. Neglect of repairs is *permissive* or *omissive* waste; actual in jury is *voluntary* or *commissive* waste. *Equitable waste*, comprehends acts not deemed waste at Common Law. The remedy for waste is by action of trespass on the case, by the person in reversion or remainder; this action may be maintained by one having any immediate interest in expectancy; it may be had not only against the tenant, but against any stranger who has committed an act of waste; and will also lie at the suit of one joint tenant or tenants in common against another. An analogous action, called an action for *dilapidations*, may be maintained by a rector or vicar against his predecessor or the executors of his predecessor: and this for *permissive*, as well as voluntary waste.——*Waste land*, a tract not in cultivation, and producing little or no useful herbage or wood. About the end of the last century there were six millions of acres of such land in Great Britain; of which four millions might be brought under the plough; and most of the remainder might be used for growing wood, but much of this has since been enclosed.

WATCH (*wæce: Sax.*), in the Marine, denotes the space of time during which one division of the ship's crew remains upon deck to keep watch, the crew being generally divided into two, or in large ships, into three parts, for this purpose. The watches are termed *starboard* and *larboard* watches. The period of time called *a watch*, is four hours, the reckoning beginning at noon or midnight. There are also what are called *dog-watches*, which last only two hours, and are formed by the division of the watch between four and eight, P.M., into two parts, to break the constant recurrence of three watches at the same hours. ——To *set the watch*, is to appoint that division of the crew which is to enter on the watch.——To *relieve the watch*, is to relieve those on duty, by changing the watch.——*Watch-bill*, a list of the officers and crew who are appointed to the watch; together with the several stations to which each man belongs.——*Watch*, a pocket instrument for measuring time, in which the machinery is moved by a steel spring, coiled up, and acting by various ingenious contrivances. The spring is in a brass box called the barrel; and is combined with a tapering fusee, on which a connecting chain is wound by the key. The spring being fastened at one end to the barrel, and at the other end to an arbor or axle, unwinds off the fusee, turning it, and keeping the watch going; while the action of the fusee accommodates itself, by its varying size, to the varied energy of the spring. [See FUSEE.] The force being thus produced, other wheels are put in motion; and time is exactly measured by the hands on the dial. The watch manufacture consists of almost innumerable departments. When executed in a more perfect manner, for the purposes of navigation, watch is termed a *chronometer* [which see]. Watches are said to have been first made at Nuremberg, as early as 1477; they were originally of various shapes, and must have been very imperfect until the invention of the spiral spring as a regulator to the balance, which took place about the year 1658. The Swiss trade in watches is very considerable; the works are manufactured by the female peasants in the mountainous districts, and are put together in the towns.

WATCH AND WARD (*wæcce*, to watch; and *weærdian*, to guard: *Sax.*), the custom anciently observed of watching by night, and warding or keeping the peace by day in towns and cities, which was first appointed by Henry III. The word *watch*, properly applied to the night; *ward*, to the day.

WATER (*wæter: A.-Sax.*), a transparent and colourless compound fluid, destitute of smell, nearly without taste, and almost incompressible—a pressure equal to 2000 atmospheres occasioning a diminution of only one-ninth of its bulk. It is composed of two substances, neither of which can be exhibited separately, except in the gaseous form; and when aeriform, they are known, the one as hydrogen gas, or inflammable air; the other as oxygen gas, or vital air. These gases, in the proportion of about two measures of hydrogen to one of oxygen, when united chemically, and reduced from the form of air to that of a liquid, constitute the fluid we call *water*. It passes to the solid state at 32° Fahr. When it shoots into ice, it forms in the first place a prism, not very regular in shape, but very long; and undergoes an enlargement in volume. In the act of freezing, too, the greater part of the air, which the water holds loosely dissolved, is expelled. At 212°, under a medium atmospheric pressure, water boils, but returns unaltered to its liquid state on resuming any temperature below this point. All water which has been exposed to the atmosphere (as spring and river water) contains a portion of air, from which it derives a sparkling quality and agreeable taste. It is thus also fitted for supporting the respiration of fishes. A strong attraction is exerted between water and the fixed alkalies, so also between it and the alkaline earths. From the extensive solvent power of water, it is scarcely ever met with pure in nature; every kind being impregnated either with saline, earthy, or mineral substances. The simple waters are the following:—1. *Distilled water*. This is the lightest of all others, containing neither solid nor gaseous substances in solution, is perfectly void of taste and smell, colourless and transparent, has a soft feel, and wets the fingers more readily than the other. As it freezes exactly at 32° of Fahrenheit, and boils at 212° under the atmospherical pressure of 29·8 inches; these are made use of as the standard points for thermometrical division; and its weight being always the same under the mean pressure and temperature, it is employed for the comparative standard of specific gravity. 2. *Rain water*, the next in purity to distilled water, is that which has undergone a natural distillation from the earth, and is condensed in the form of rain. It so nearly approaches absolute purity, when unmixed with the sulphate of lime and calcareous matter which it imbibes when it falls in towns, from the mortar and plaster of the houses, as probably to be equal to distilled water for every purpose except in the nicer chemical experiments. 3. *Ice* and *snow-water*. This equals rain-water in purity, and when fresh melted, contains no air, which is expelled during congelation. 4 *Spring-water*. Under this comprehensive class are included all waters that rise from some depth beneath the soil, and are used at the fountain head, or at least before they have run any considerable distance, exposed to the air. When the ingredients are not such as to give any peculiar medicinal or sensible properties, it is distinguished as a hard or a soft spring, sweet or brackish, clear or turbid, or the like. By far the greater number of springs are cold; but as they take their origin at some depth from the surface; and below the influence of the external atmosphere, their temperature is, in general, pretty uniform during every vicissitude of season, and always several degrees higher than the freezing point. The water of deep wells is much harder than that of springs which overflow their channel; for much agitation and exposure to air produce a gradual deposition of the calcareous earth, and hence spring water often encrusts to a considerable thickness the inside of any kind of tube through which it flows, as it arises from the earth. The specific gravity of these waters is also, in general, greater than that of any other kind of water, except that of the ocean. Springs that overflow their channel, and form to themselves a limited bed, pass insensibly into the state of river water, and thus become altered in some of their chemical properties. 5. *River water*. This is in general much softer and more free from earthy salts than the last, but contains less air of any kind; for, by the agitation of a long current, and in most cases a great increase of temperature, it loses common air and carbonic acid, and much of the lime which it held in solution. Its specific gravity, in this way, becomes less, its taste is not so harsh, but less fresh and agreeable, and out of a hard spring is often made a stream of sufficient purity for most of the purposes where soft water is required. Some of the mountain lakes and rivulets, however, which take their rise from a silicious rock, and flow in a sandy or stony bed, are from the outset remarkably pure 6. *Stagnant waters*. These generally abound with the remains of animal and vegetable matter undergoing decomposition; and as they are usually shallow, they receive the full influence of the sun, which further promotes all the changes that are going on within them. The decidedly noxious effects produced by the air of marshes and stagnant pools have often been supposed to extend to the internal use of these waters. It ought, however, to be observed that they are generally soft, and many of the impurities are only suspended, and therefore separable by filtration. 7. *Mineral waters*, are unfit for common purposes; and derive their peculiar properties from the substances which they hold in solution. But there are some, such as Malvern water, remarkable only for extreme purity. Mineral waters are of various kinds. [See MINERAL WATERS.] Some are effervescent or sparkling, from containing carbonic acid. Chalybeate springs are more or less tonic and astringent. Saline springs aperient and alterative. Mineral waters contain their active ingredients in very minute quantities. Much of the advantage to be derived from a course of mineral waters is, undoubtedly, due to the strict attention paid to diet, to bodily exercise, mental relaxations, and regular hours; and, in some cases, to the diluent effects of pure water—which explains the advantage of that of Malvern, in calculous complaints, &c. The great reservoirs of water on the globe are the ocean, seas, and lakes, which cover more than two-thirds of its surface; from these, it is raised by evaporation: and uniting with the air in the state of vapour, is wafted over the earth, ready to be precipitated in the form of rain, snow, or hail. *Sea water* is remarkably constant in the nature and relative quantities of its ingredients. Its spec. grav. is very considerable, since it contains more than *three per cent.* of solid matter; which consists chiefly of common salt, chloride of magnesia and lime, together with traces of chloride of potassium, chloride of ammonium (sal ammonia) carbonate of lime, bromide, and often iodide of magnesium. [See ATMOSPHERE, HYDROGEN, OXYGEN, GAS, RAIN, RIVERS, &c.] ——In Manufactures, a certain appearance, imitating water: produced on silks, mohairs, &c Watering causes the exhibition of a variety of undulated reflections, and plays of light.——WATER, in Marine phraseology, denotes the state of the water at sea: as *high-water*, *low water*, *foul water*, *dead-water*, &c ——WATER, in Mineralogy, a term used by lapidaries for the lustre of precious stones.——*Water of separation*, a name given by refiners to aqua fortis, because it separates gold from silver.

WATER BAILIFF, in Law, an officer in seaport towns who searches ships.

WATER-BETONY, the *Scrophularia aquatica* of botanists, a perennial.

WATER-COLOUR PAINTING, that in which the colour is levigated with water and gum. It has been latterly carried to great perfection, and nearly rivals oil-painting in everything but durability.

WATER-COURSE, any natural or artificial stream of water; as a river, a canal, and the like.

WATER-CRESS, the *Nasturtium officinale* of botanists, nat. ord. *cruciferæ*, a perennial plant that grows on the margin of clear streams, or even partly immersed in the water. Great quantities are consumed as salad; and of late years it has been cultivated to a considerable extent. The plant is also employed in medicine as an antiscorbutic.

WATER-DEVIL, a name given by some to the Larva of a British beetle, a species of *Hydrophilus*.

WATER-GAVEL, in old writers, a rent paid for fishing, or any other benefit received from some river.

WATER-GLASS, a solution of silicated

soda, which is sometimes obtained by dissolving broken flints in a solution of caustic soda at a temperature of 800° F., assisted by pressure. Another mode of producing soluble glass is to melt together, in a reverberating furnace, white sand and dry carbonate of soda. After six hours of strong firing, the melted charge runs out as perfect glass, from which bottles, &c., may be blown and moulded. Boiling water, however, dissolves this glass. Some of the uses of water-glass are mentioned under STEREOCHROME and STONE, ARTIFICIAL. It is also employed in the manufacture of soap to the saving of oil and tallow.

WA'TER-LEVEL, a contrivance for finding the level of roads or grounds, by means of a surface of water or other fluid, founded on the principle that water always finds its own level. It consists of a long wooden trough, which, being filled with water, shows the line of level.

WATER-LILY, the name of some aquatic plants belonging to the genus *Nymphæa*, the flowers of which are large, and contain numerous petals, so as to appear double. In the morning, they raise themselves out of the water to expand, and close again, reposing upon the surface, in the afternoon.

WA'TER-LINE, a horizontal line supposed to be drawn about a ship's bottom, at the surface of the water. When the cargo is on board, it is called the *load water line;* otherwise, the *light water line*.

WA'TER-LOGGED, a term applied to a ship when, by leaking, and receiving a great quantity of water into her hold, she has become so heavy as to be totally unmanageable. Having lost her buoyancy, she yields to the effect of every wave passing over her deck.

WA'TER-MARK, the utmost limit of the rise of the flood.——The mark visible in paper, and which is made in the manufacturing. [See PAPER.]

WA'TER-MELON, the *cucumis citrullus* of botanists, a plant belonging to the nat. ord. *cucurbitaceæ*. To bring it to perfection, this plant requires a warm climate, and a dry, sandy, warm soil. The fruit is remarkably rich, and it abounds with a sweetish liquor.

WA'TER-MILL, a mill whose machinery is moved by water: and thus distinguished from a wind-mill, steam-mill, &c. Water-mills for grinding corn were invented by Belisarius, while besieged in Rome by the Goths, 555.

WA'TER-ORDE'AL. [See ORDEAL.]

WA'TER-ORME, in the Marine, an epithet for the state of a ship which has barely a sufficient depth of water to float her off the ground.

WA'TER-POISE, in Mechanics, an instrument formerly used for trying the strength of liquors; the hydrometer, &c., are now employed for the purpose.

WA'TER-SHED, the line of, or the ridge line of a district, is that line from which the ground slopes downwards on each side. Rain falling on this line will run in opposite directions. Such a line divides one river-basin from another, and one valley from another. Its course is usually very irregular both in altitude and azimuth.

WA'TER-SHOOT, in Botany, a sprig which springs out of the root or stock of a tree.

WA'TER SPOUT, an aqueous meteor, most frequently observed at sea; rising at first in the form of a small cloud, which afterwards enlarges, and, assuming the shape of a cone, with its apex downwards, is driven furiously by the wind, and is often accompanied with thunder and lightning; causing destruction, when it bursts, to whatever happens to be within the sphere of its action. When it appears at sea, there are generally two cones, one projecting from the cloud, the other from the water below it; and they sometimes unite, their union having been observed to be accompanied with a flash of lightning; but more usually disperse while separate. It is probably caused by a whirlwind of extreme intensity.

WA'TER-TABLE, in Architecture, a projection or horizontal set-off, in a wall, intended to throw off the water from the building.

WA'TER-WAY, in a ship's deck, a piece of timber, forming a channel for conducting water to the scuppers.

WATER-WHEEL, in Hydraulics, an engine for raising water: [See PERSIAN WHEEL]. Also a wheel turned by the force of water, and used for giving motion to machinery. The water-wheel is of two kinds; the *vertical* and the *horizontal*, or turbine [which see]. Vertical water-wheels are either over shot, under shot, or breast wheels. The *overshot wheel* is moved almost entirely by the weight of the water, which it receives and retains for some time in its buckets. The *undershot wheel* is moved almost entirely by the momenture of the water, which strikes against its floatboards. The *breast wheel* is moved both by the weight and momenture of the water, which it receives at about half its height, and which is retained by its floatboards and the curved masonry behind them, until it passes out, under the wheel below.

WA'TER-WORKS, in general, denote every description of machinery employed in raising or sustaining water; in which sense, water-mills of all kinds, sluices, aqueducts, &c., may be so called. The term water-works, however, is more particularly used for such machines as are employed only in raising water.

WA'TER OF CRYSTALLIZA'TION, that definite quantity of water which enters into the composition of most crystallized salts, and without which they cannot retain their crystalline form. It is not necessary to crystallization in all cases: thus crystals of nitre and sulphate of potash contain no water; on the other hand, some crystallized salts contain so much, that, when heated, they melt in it, forming in reality hot salinated solutions.

WAT'TLE, the fleshy excrescence that grows under the throat of a cock or turkey or a like substance on a fish. Also, a twig or flexible rod. Also, a name given to certain species of *Acacia* in Australia.

WAVE (*wæge: A.-Sax.*), the alternate elevation and depression of the surface of a fluid. When this surface is pressed down at any part, the adjoining parts rise, but sink again by the action of gravity; and, acquiring a velocity due to their height, descend below the original level, communicating in their turn a pressure to others near them, which rise and sink in a similar way; and thus a reciprocating motion is produced. When the depth is sufficient to allow the oscillations to proceed unimpeded, no progressive motion of the fluid takes place; but, when free oscillation is prevented by a shelving shore, the interposition of a rock and the columns in deep water are not balanced by those in shallower, and therefore acquire a progressive motion towards the latter, forming *breakers*. When caused by the agitation of a small portion of the fluid, by, for example, a stone thrown into it, the waves appear to advance in concentric circles, their height diminishing as they proceed; but there is no progressive motion of the fluid itself, as will be shown by any light body floating on its surface. The whole seems to roll onward, but in reality each particle of water only oscillates with a vertical ascent and descent. Two sets of waves will cross each other without any mutual interruption. Waves meeting with an obstacle, such as a wall, &c., will be reflected backwards, according to the laws to which light and sound are subjected; if there be a small aperture in the obstacle, the waves will be propagated beyond it, and diverge as from a centre. Waves at sea, caused by the wind, have a progressive as well as an oscillatory motion; except increased by the wind suddenly veering about, they do not exceed about six feet in height; and the effect of the wind never reaches to a greater depth than about 30 or 40 feet. The progressive wave sent forward by a floating body, or generated in any other way, differs entirely in its character and phenomena from the oscillatory waves of the sea. Its velocity varies as the square root of the depth of the water; and hence a wave of high water of a spring tide travels faster than a wave of high water of a neap tide; and any change in the depth of rivers produces a corresponding change in the interval between the moon's transit and the hour of high water.

WAVED, or WAVY (same *deriv.*), in Heraldry, *indented*.

WA'VELLITE, in Mineralogy, a hydrated phosphate of alumina, called also *Hydrar*-[illegible] It is usually found in crystals, that adhere and radiate; forming hemispherical or globular concretions; from a very small size to an inch in diameter.

WAX (*weaxe: Sax.*), in Natural History, the substance with which bees build their cells. They carry the *farina* or *pollen* on their hinder legs; but, according to Reaumur, this dust does not contain any real wax; nor is this latter substance produced by the mixture of the farina with a glutinous liquor, by trituration, or by any other mechanical process. In reality, it constitutes the food of the *Larvæ*. After long and attentive observation, this naturalist found, that when bees eat the pollen, it is converted, by an animal process, into wax: bees fed entirely on sugars will still produce wax. There is a wax that forms the varnish, with which the leaves of several trees are coated, and is found on some berries, as those of the *Myrica Cerifera*, forms the green fecula of many plants, particularly of the cabbage, and may be extracted from the pollen of most flowers; but it slightly differs from bees' wax. The latter is the secretion of a certain organ, situated on the sides of the median line of the abdomen of the bee: each individual has eight wax sacs or pouches. Wax from the comb has the smell of honey, and is of a yellow colour. It is purified and bleached, by melting it with hot water or steam, and then exposing it in thin ribbons to the action of air, light, and moisture. When purified, wax is white, and, if in thin segments, translucent; it has neither taste nor smell; its specific gravity is about 0·963. It liquefies at 154·5° Fahr.; but it becomes plastic at 86°; at 32° it is hard and brittle. It consists of two substances, which are separated by boiling alcohol, one of them, *myricin*, being left behind. The alcoholic solution deposits *cerin* on cooling. Both these proximate principles are composed of carbon, hydrogen, and oxygen. Wax is often adulterated with starch; this may be detected by oil of turpentine, which dissolves the wax, and leaves the starch. It is still more frequently adulterated with mutton suet, this is detected by dry distillation; when, if tallow is present, sebacic acid will be formed, and will cause a precipitate on acetate of lead. It is also adulterated with stearine or stearic acid; this may be detected by the odour of tallow, caused by heating it highly; also by its crumbly texture. Lastly, it is adulterated with spermaceti, which takes away its peculiar pearly lustre, and renders it more soft and fusible. [See BEE.]

WAX-FOSSIL, or *Ozokerite*, a brownish mineral, found in Moldavia, having several of the characters of bees' wax.

WAX-MYRTLE, in Botany, the *Myrica cerifera*, or Bay-berry, a North American shrub, the berries of which are covered with a greenish wax, called myrtle-wax, or bay-berry tallow; it is slightly different from bees' wax. [See WAX.]

WAX-PALM, in Botany, the *Ceroxylon andicola*, a species of palm growing on the Andes, the stem of which is covered with a secretion, consisting of two-thirds resin and one-third wax.

WAX'-WORK, figures formed of wax, in imitation of real persons. Wax is used with great success in representing *anatomical* details.

WAY, the Nautical term for progress; when a ship is advancing, she is said to have *way* upon her: when stationary, to have *no way*.

WAYS AND MEANS, the financial resources to meet the public expenditure; or supplies voted by parliament.

WEALD-CLAY (*weald*, a wood or grove: *A.-Sax.*), in Geology, a tenacious blue clay, which forms the sub-soil of the wealds of Kent and Sussex. In it are contained subordinate beds of sandstone and shelly limestone, with layers of septaria of argillaceous iron-stone. The *Wealden strata* include the Weald-clay (freshwater) and the Hastings sand group (marine). They form the inferior division of the lower Cretaceous or Neocomian series.

WEATHER (*wether: Sax.*), the state of the air or atmosphere with respect to heat or cold, wetness or dryness, calm or storm, &c. [See AIR, ATMOSPHERE, CLOUD, RAIN, STORMS, &c.] Mankind, in all ages, have supposed that the weather is influenced in some way by the moon. This belief, however, has no foundation; for she cannot act on the earth by *reflecting* the solar rays, since her light is only the 100,000th part of that of the sun; and the heat she causes is utterly inappreciable; nor by her *attraction*, since the effect of this on the air, which has so little density, must be extremely feeble; nor, lastly, by some obscure emanation, since the most careful meteorological observations have never detected any such thing. The registers kept at the various observatories show that the moon's phases are not connected in any way with the weather.

WEATH'ER CLOTHES, in a ship, long pieces of canvas or tarpauling used to preserve the hammocks from injury by the weather when stowed; or to defend persons from the wind and spray.

WEATH'ER-GAUGE, or **WEATH'ER-GAGE**, a naval term; a ship is said to have the *weather-gauge* of another when she is at the windward of her.

WEATH'ER-HELM. A ship is said to carry a *weather-helm* when she is inclined to come too near the wind.

WEATH'ERING, a geological term, signifying the action of meteoric influences (rain, frost, the oxygen of the atmosphere, &c.) upon the crust of the globe. This action is always one of degradation.

WEATH'ER-TIDE, the tide which sets against the lee side of a ship, impelling her to windward.

WEAV'ER BIRDS, the popular name given to a tribe of birds belonging to the finch family, on account of the skill they display in forming their nests. They are natives of hot climates in the old world. The common weaver bird (*Ploceus Baya*) lives in India, and constructs a pendent nest shaped like a retort, specimens of which are often seen in museums. It usually hangs from the leaf of a tall palm tree. The grasses or leaf strips of which it is composed are very artistically plaited together, and so substantial as to defy the heaviest rains of the monsoons. The Whydah (or Widow) birds, of the western coast of Africa, belong to this tribe.

WE'AVING (*wevan*, to weave: *Sax.*), in Manufactures, the act or art of forming cloth in a loom, by the union or intertexture of threads; which is done by crossing the threads by means of a shuttle. The threads first laid in length are called the *warp;* those which cross them in the direction of their breadth are called the *weft* or *woof.* Weaving is an art of great antiquity, and gives employment in all nations to a large portion of the population. In England, Leeds is the centre of woollen cloth weaving; Manchester of cotton weaving; Macclesfield of silk weaving; Nottingham of stocking weaving; and Kidderminster of carpet weaving. The machinery used for weaving in the earliest times, though perhaps rude in its construction, was, in principle, similar to that still in use; and the process of fulling and preparing the cloth seems to have resembled the modern practice in every particular, except that of shearing the nap, with which the ancients do not appear to have been acquainted. Muslins are to this day manufactured by the primitive loom in India, probably without alteration of the form in use during the earliest ages of its invention. In ancient times, it is probable that only enough cloth to form a single dress was woven at once; since ancient records do not speak of its being sold by measure. The manufacture of flexible stuffs by means of machinery, operating on a large scale, is an invention of the last century; it has given birth to some of the most elaborate combinations of mechanism, and constitutes an important source of our national wealth. The jaquard loom, a most admirable contrivance for saving time and simplifying the process of weaving silks, &c., in complicated patterns, is likely to be superseded by a more simple machine, in which electro-magnetism is most ingeniously applied to the production of complicated movements.

WEB'-FOOTED, in Natural History, *palmiped*, or having feet like a goose or duck.

WEDGE (*wegge: Belg.*), in Geometry, a prism with triangular bases.——In Mechanics, one of the six mechanical powers, reducible to the inclined plane, and governed by the same laws. It is used sometimes for raising bodies, but more usually for dividing or splitting them; in the former case, the wedge is pushed under the body to be raised, but the effect is still that of an inclined plane, for the result is the same, and is estimated in the same way, whether the wedge is pushed *under* the load or the load is pushed *over* the wedge. When a wedge is driven forward by percussion, the power which acts upon it cannot be estimated with accuracy, on account of the friction, which is very considerable. This, however, is greatly diminished, for an instant, by the tremour caused by the blow; cutting and piercing tools are generally constituted on the principle of the wedge.

WED'NESDAY (*wodensday: Sax.*), the fourth day of the week; consecrated by the Scandinavians to Woden, a deity that corresponded with Mercury of the Greeks and Romans.——*Ash Wednesday*, the first day of Lent. Some think the day to have received this name from the custom in the early ages of the church, of penitents appearing in sackcloth and with ashes on their heads.

WEED (*weod*, tares: *Sax.*), the general name of any plant that is noxious or useless. The word therefore has no definite application to any particular plant or species of plants; but whatever kinds spring up in fields or gardens that are injurious to crops come under the appellation of *weeds*.

WEEK (*weoc*: *Sax.*), a cycle of seven days; the first day, Sunday, being the Christian festival to celebrate the Resurrection; and the seventh, Saturday, being the sabbath of the Jews. [See SATURDAY and SUNDAY.] The Greeks did not divide the year into weeks, nor the Romans, until after the reign of Theodosius. Some believe this division to have been suggested by the phases of the moon; but others, with greater probability, by the seven planets known in ancient times, the days of the week being universally called after them. The Latin names of the days are still retained in legislative and judicial acts in this country.

WEE'VIL (*wefel*, a grub: *Sax.*), in Entomology, a small coleopterous insect of the *curculionidæ*. The corn-weevil (*calandra granaria*) does great damage to wheat or other corn, by eating into the grain and devouring the farinaceous parts.

WEIGHT (*wægan*, to weigh: *Sax.*), in Experimental Philosophy and Commerce, the measure of the force by which any given portion of matter gravitates to the earth. The determination of weight, like that of extension, consists in comparison with some known standard. Two kinds of weight are used in England, the *avoirdupois weight*, in which the pound consists of 16 ounces, each ounce containing 437½ grs., in all 7,000 grs.; and the *troy weight*, in which the pound is divided into 12 ounces, each ounce containing 480 grs., in all 5,760 grs. *Apothecaries weight* is troy weight differently divided. The unit of French weight is a *gramme*, equal to 15·434 grs.——*Weight*, in Mechanics, the resistance to be overcome by a machine.

WEIR (*wer*: *A.-Sax.*), an embankment or dam of stone or timber placed across the channel of a stream for various purposes, such as the supplying a mill with water at a dry season, or the production of a reach of deep water for vessels where the river is shallow.

WELD, the *Reseda lutea* of botanists, a wild British plant, the stalk and root of which are used in dyeing bright yellow and lemon colours.——*Weld* (*æld*, fire: *Sax.*), in Ironworks, to unite or hammer into firm union two pieces of metal softened by heat.

WELL (*welle*: *Sax.*), a cylindrical excavation sunk perpendicularly into the earth to such a depth as to reach a supply of water, and walled with stone or brick to support the earth. [See ARTESIAN WELLS.]——*Well*, in the Military art, a shaft which the miner sinks under ground, with branches or galleries running out from it, either to prepare a mine, or to discover and counteract the enemy's mine.——In Ship-building, a small enclosed place, near the mainmast; extending from the bottom of the ship to the principal gun deck and containing the pumps.

WELLINGTO'NIA, is the botanical name of a lofty coniferous tree, an inhabitant of California. A specimen was found of the enormous height of nearly 400 feet, and the age of it was estimated at 4,000 years.

WER'EGILD (*Sax.*), in Anglo-Saxon Law, the *were*, or compensation paid by a delinquent to the party wronged, or his relations, for injuries committed against the person. The *eorls*, or nobility, were to be paid six times as much as the *ceorls*, or commonalty. Weregild was usual among all the Teutonic and many of the Celtic tribes, and is mentioned by Tacitus in his account of the ancient Germans.

WER'NERITE, a mineral, consisting of silicate of alumina, lime, and oxide of iron. It is found massive, and crystallized in octahedral prisms with four-sided pyramidical terminations, disseminated in rocks of feldspar. It is of a grayish or olive-green colour, with a pearly lustre, and melts into a white enamel.

WEST (*Sax.*), one of the cardinal points, being that point of the horizon where the sun sets at the equinox, or any point in a direct line between the spectator or other object, and that point of the horizon. In a less strict sense, it is that region of the hemisphere near the point where the sun sets when in the equator.——Formerly the empire of Rome was called the empire of the *West*, in opposition to the empire of the East, the seat of which was Constantinople.

WHALE (*hwale*: *Sax.*), the name of some cetaceous marine mammals belonging to the families *Balænidæ* and *Physeteridæ* of zoologists. The latter include the SPERM whale family. In the former are placed the genera *Balænoptera* (see RORQUAL) and *Balæna*. The latter genus, distinguished by the absence of a dorsal fin and by the smoothness of the belly, includes the Greenland or Right Whale (*B. mysticetus*), so much sought after for the oil extracted from its blubber, and for the material termed whale-bone, which forms plates in the upper jaw. This whale has been taken nearly 100 feet long. Animals of such enormous strength and magnitude, we might imagine, would spread terror and devastation all around them, and make an indiscriminate slaughter of the inferior tribes. No creature, however, is less voracious than the common whale; little animal substance is ever found in its stomach; it feeds, as some allege, upon different insects that float on the surface; according to others, upon the medusa or sea-blubber. Its food, we are certain, must be minute, for the capacity of its throat does not exceed four inches! a size beyond all proportion smaller than that of other large aquatic animals. To a slender appetite the whale adds peaceable and harmless manners; it pursues no other inhabitant of the waters, but leads an easy and quiet life on the bosom of the waves, and is inoffensive in proportion to its ability to do mischief. [See FISHERIES.]

WHEAT (*hwæte Sax.*), a plant of the genus *Triticum*, and the seed of the plant, which furnishes a white flour for bread, and is the grain most generally used by the human race, except in those countries where rice forms the principal article of food. The varieties of wheat are numerous, though the difference between each kind is not very remarkable. The culture of wheat, from time immemorial, and in different soils and climates, has produced these varieties; the chief and most permanent of which are the red and white grained, and the spring wheat, which is generally red. Wheat yields a greater proportion of flour than any other grain, and is also more nutritive. Gluten is so essential an ingredient in bread, that fermentation cannot go on without it; hence the inferiority of wheat in wet seasons, and when it is blighted or ill ripened, this element being then deficient in quantity; and hence also the advantage of having a stock of old grain. The straw of wheat, from dry, chalky lands, is manufactured into hats. Leghorn hats are made from a bearded variety of wheat, not unlike rye, raised on poor sandy soils, on the banks of the Arno, between Leghorn and Florence, expressly for this manufacture. It does not grow above eighteen inches in length, is pulled green, and bleached, like flax, on the gravelly bed of the river. The straws are not split, which renders the plait tougher and more durable.

WHEAT'EAR, the English name of the *Saxicola œnanthe* of ornithologists, a small bird belonging to the same family as the redbreast and redstart; called also *white-tail* and *fallow finch*. It comes to our shores in the spring, and being an excellent article of food, immense numbers are annually taken, particularly on the South Downs of Sussex.

WHEEL (*hweol: Sax.*), in Mechanics, a simple machine, consisting of a round piece of wood, or metal, which revolves on an axis. The wheel has an important place in most engines; it is of an assemblage of wheels that most engines are composed. The centre of a wheel is like the fulcrum of a lever, and a simple action merely transfers the force on one side to the other side; but if wheels are so connected as to diminish velocity, then power is gained.——*Wheel*, in the military art, is the word of command, when a battalion or squadron is to alter its front either one way or the other. An order to *wheel to the right*, directs the man in the right angle to turn very slowly, and every one to wheel from the left to the right, regarding him as their centre; and *vice versâ*, when they are to *wheel to the left*.——*Wheel*, in a ship, the wheel and axle, which move the tiller.——*Water-wheel*, in Hydraulics, one used to obtain a motive power from water. [See WATER-WHEEL.]

WHEEL-WORK. Of all the modes of communicating motion, the most extensively useful is the employment of wheel-work; which is capable of varying its direction and its velocity without any limit. When the pressure on the machinery is not very considerable, the wheels and axles are allowed to work by the friction of their surfaces, which is increased by cutting the wood so that the grains of the surfaces in contact shall run in opposite directions; also by gluing buffed leather upon the surfaces of the wheels and axles. There are other ways of transmitting the force of each axle to the circumference of the succeeding wheel, when the work to be done requires considerable force. One of these is, by ropes, straps, bands, or belts, which are placed round the circumference of the wheels that are to act upon each other. The action is in this manner transmitted by the tension of the band, &c., and rendered effective by friction with the circumferences on which it is rolled. Wheels and axles connected in this manner are called *band-wheels*. When this method is used, a wheel may communicate a motion, which may be either *direct* or *reverse*, also more or less rapid, to another at a considerable distance; and the relative velocities may be alterable *at pleasure*, by using two frusta of cones, the narrow end of one being placed opposite to the wide end of the other. When any machinery is to be occasionally thrown out of action, the wheel or *drum* which drives it, is capable of connection with either a *fast*, or a *loose pulley*; in the former case, motion is communicated to the machinery; in the latter, the loose pulley only is turned round by the prime mover, when bands would be liable to slip from want of sufficient friction, on account of the greatness of the resistance; or when a very accurate motion is required, toothed wheels are used. [See TEETH OF WHEELS.] The teeth are sometimes cast on the wheel, sometimes are fixed to it, and sometimes are cut by machinery. When two wheels of very unequal size act together, the larger is termed a wheel, and the smaller *pinion* wheels, are denominated spur, crown and bevel gear, according to the position of their teeth. If the latter are perpendicular to the axis of the wheel, and in the direction of its radii, it is called a *spur-wheel*. If the teeth are parallel to the axis of the wheel, and therefore perpendicular to its frame, it is called a *crown-wheel*. Two spur-wheels, or a spur-wheel and pinion which work in one another, are always in the same plane, and have their axes parallel; but when a spur and crown-wheel are in connexion, their planes and axes are at right angles. When the teeth are oblique to the plane of the wheel, it is called a *bevel-wheel*, the use of which is to produce a rotatory motion round one axis, by means of a rotatory motion round another which is oblique to it; when the axes are at *right angles*, the wheels used are termed *mitre wheels*. When a varying velocity is to be produced by a uniform force, *excentric square*, and other shaped wheels are sometimes made to act together; they remain connected on account of the sum of the radii of the parts, actually in contact, being always the same. An arrangement is sometimes made for separating wheels which are intended to turn each other, and for reconnecting them at pleasure; the wheel are said to be thrown by these operations *out of gear* and *into gear* again. One of the simplest modes of effecting this is to slide one of the wheels along its axis, so that it ceases to be opposite to the other.

WHEEL AND AXLE, in Mechanics, one of the mechanical powers, reducible to the *Lever*. It consists of a wheel, at the circumference of which the power acts, and an axle, at the circumference of which the weight acts. Provided the power, in moving, describes a circle, a wheel is not required, a winch handle, &c., will answer instead of it. The wheel and axle form a lever with unequal arms, which never gets out of action; or more strictly, a series of levers which have a common centre; but of which only one acts at a time, that one whose arms are, at the moment, perpendicular to the direction of the power and weight. When there is equilibrium, the power multiplied by the radius of the circle which it describes, is equal to the weight multiplied by the radius of the axle. The mechanical effect of this machine may be increased either by increasing the radius of the wheel or diminishing that of the axle.

WHEEL, BREAKING ON THE, a punishment formerly inflicted in France and other countries. It consisted in fastening the criminal to a cartwheel, or a frame made in the form of a St. Andrew's Cross; the executioner then broke his legs with blows of an iron bar, and sometimes caused his immediate death with blows on the chest or stomach, called *coups de grace* (merciful blows). He was then left to expire, if not already dead, with his legs doubled up under him. Sometimes the criminal was strangled after the first two or three blows.

WHEELS OF CARRIAGES. Wheels are applied to carriages for the purpose of diminishing friction, and causing them to pass over elevations or depressions in the road more easily. The larger the wheel the less the friction; also the less it sinks into a rut, and the more easily it is drawn over an obstacle, since the longer the curved inclined plane, along which the centre of gravity, or, which is the same thing, the centre of the wheel, is lifted in passing over it, the radius of this curve being the radius of the wheel.

WHEE'ZING (*hiveosan*, to breathe with difficulty: *A.-Sax.*), in the Veterinary Art, a disordered respiration in horses; arising from the narrowness of the bronchial passages.

WHELK, the *Buccinum undatum* of Conchologists, a gasteropod mollusc with a spiral shell, common on our coasts, and used extensively for human food and for bait.

WHET'STONE (*hwettan*, to whet: *Sax.*), or Novaculite (*novacula*, a whetstone: *Lat.*), in Mineralogy, so called from its property of whetting or sharpening steel. It is a talcy slate, containing silica; to the particles of which, though not perceptible, its efficacy is due.

WHEY (*hwæg*: *Sax.*), the serum or watery part of milk, which remains after the cream and coagulable matter of that fluid are removed, either by churning, or by separating it with rennet, vinegar, cream of tartar, &c.

WHIG (same *deriv.*), one of a political party which had its origin in England in the 17th century, in the reign of the Stuarts, when great contests existed respecting the royal prerogatives. Those who supported the king in his high claims were called *Tories*, and the advocates of popular rights were called *Whigs*. The name was given to the latter, on account of their principles being considered insipid by the Tories, who advocated absolute power and indefeasible hereditary rights in the monarch. [See TORY.]

WHIN DYKES, in Mineralogy, dykes, banks, or natural walls of whin-stone; a species of basalt, found in various parts of the world, but nowhere on so grand and stupendous a scale as on the Scotch and Irish coasts.

WHIP-POOR-WILL, the *antrostomus vociferus* of ornithologists, one of the goat-suckers, a nocturnal bird of North America, which derives its name from its cry. When engaged in its nightly rambles, it is seen to fly within a few feet of the surface of the earth, in quest of moths and other insects. During the day these birds retire into the darkest woods, where they pass the time in silence and repose, the weakness of their sight compelling them to avoid the glare of light.

WHIRL POOL, a vortex where the water moves round in a circle. Those in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. The most celebrated of these are the Euripus, near the island of Eubea, in the Grecian Archipelago; Charybdis, in the strait between Sicily and Italy; and the Maelstrom, off the coast of Norway. Their dangers seem to have been exaggerated. They are produced by the meeting of currents, which run in opposite directions.

WHIRL'WIND, an exceedingly rapid and impetuous wind that rises in a whirling direction, and continues in the same way for some time. Whirlwinds have both a progressive and a circular motion; they usually rise after calms and great heats; and occur chiefly in the warmer latitudes. [See WIND, STORMS, &c.] They are ascribed by some to electricity, but are considered by others as formed by the meeting of currents of air which are moving in opposite directions in the same manner as whirlpools are produced in water.

WHIS'KEY, a well known spirituous liquor, distilled generally from barley; but sometimes from wheat or maize, as is the case in the United States. The word is a corruption of the first part of a Celtic phrase which signifies 'water of life.'

WHIST, the most perfect game at the card table, requiring great attention and silence, whence its name. It is played by four persons, who cut for partners; the two highest and the two lowest are together, and the partners sit opposite to each other; the person who cuts the lowest card is to deal first, giving one at a time to each person, till he comes to the last card, which is turned up for the trump, and remains on the table till each person has played a card. The person on the left-hand side of the dealer plays first, and whoever wins the trick is to play again, thus going on till the cards are played out. The ace, king, queen, and knave of trumps are called *honours;* whichever side holds three of these honours reckons two points towards the game, or for the whole of the honours four points, the game consisting usually of ten points. The honours are counted after the tricks; all above six tricks reckoning towards the game.—— In this game, *finessing* means endeavouring to gain an advantage thus; when a card is led, and you have the best and third best of that suit, you put your third best card upon that lead, and run the risk of your left-hand adversary having the second best; if he has not, which is 2 to 1 against him, you are then sure of gaining a trick. *Forcing* means obliging your partner or adversary to trump a suit of which he has none. *Long trump* means having one or more trumps in your hand, when all the rest are out. *Loose card* is a card of no value, and consequently the most proper to throw away. *Points*, ten of them make a game of *long;* and five, of *short* whist; those gained both by tricks and honours are scored, but tricks count *before honours*, when one party would win the game by the former, and the other by the latter. *Tierce*, or Terce, is a sequence of any three cards, immediately following one another in the same suit. *Tierce-major* is a sequence of ace, king, and queen. *Quart* is a sequence of any four cards, immediately following each other in the same suit. *Quart-major* is a sequence of ace, king, queen, and knave. *Quint* is a sequence of any five cards immediately following one another in the same suit. *Quint-major* is a sequence of ace, king, queen, knave, and ten. *Reverse* means only playing the hand in a different manner; that is, if you are strong in trumps you play one away; if weak in trumps you play the reverse, viz. another. *See-saw* is when each partner trumps a suit, and plays those suits to one another, for that purpose. *Score* is the number of points set up towards the game. *Slam* is when either party wins every trick. *Tenace* is having the first and third best cards, and being last player, consequently catching the adversary when that suit is played; as, for instance, in case you have ace and queen of any suit, your adversary leads, you must win those two tricks; and so on of any other tenace of inferior cards.

WHITE (*hwit: Sax.*), in Chromatics, a colour which is a combination of all the prismatic colours, those natural bodies only appearing white which reflect all the coloured rays.

WHITE BAIT, in Ichthyology, a small fish, greatly esteemed by epicures. It is supposed by some ichthyologists to be a distinct species of the herring genus, and has received from them the name of *clupea alba*, but others believe that white bait is merely the young of the sprat and other allied fishes. It begins to ascend the Thames in the beginning of April, and continues in that part of the river where the water is brackish until September. Its average length is from two to three inches

WHITE-LEAD, a pigment prepared by exposing sheets of lead to the joint action of the vapour of acetic acid, atmospheric air, and carbonic acid; and is a compound of carbonate of lead and oxide of lead. The vapour of the acetic acid merely acts as a carrier between the carbonic acid evolved from some decaying vegetable matter and the oxide of lead. White lead formed by precipitation from a solution is crystalline; and, therefore, not sufficiently opaque for the painter. White lead is often adulterated with sulphate of baryta, which is easily detected by the latter not being soluble in nitric acid.

WHITE-PRECIP'ITATE, in Chemistry, a compound of peroxide and bichloride of mercury with ammonia. It is obtained by precipitating a solution of corrosive sublimate with ammonia, and is a violent poison.

WHITE-PYRI'TES, in Mineralogy, an ore of a white colour, passing into a deep yellow and steel grey, occurring in octahedral crystals, sometimes stalactitical and botryoidal. It consists of sulphur and iron, with small quantities of manganese and silica.

WHI'TESTONE, the *Weiss Stein* of Werner, a granite, a large quantity of white felspar.

WHITE-SWEL'LING, in Medicine, a chronic enlargement of the joints, without any alteration in the colour of the skin; sometimes hard, sometimes yielding to pressure, sometimes indolent, but usually painful; and occurring in those of scrofulous habits.

WHI'TE-THORN, or HAWTHORN, the *Cratægus oxyacantha*, nat. ord. *Pomaceæ.*

WH'ITE-THROAT, the name of two small birds belonging to the Sylviadæ which visit this country in spring. The common white-throat (*Sylvia cinerea*) is much more abundant than the lesser white-throat (*Sylvia curruca*).

WHITE-VIT'RIOL, in Mineralogy, sulphate of zinc. It is found native.

WHI'TEWASH, a composition of lime and water, or of whiting, size, and water, used for whitening the plaster of walls and ceilings.

WHI'TING (*witting: Belg.*), the *Gadus merlangus* of ichthyologists, a small and delicate fish, very abundant along the northern coasts of Europe. It makes its appearance in large shoals, and is taken by the line in great numbers.——*Whiting*, chalk carefully cleared of all strong matter, ground, levigated, and made up into small cakes.

WHIT'LOW, in Surgery, *paronychia*, a swelling or inflammation about the nails or ends of the fingers, generally terminating in an abscess. Whitlows differ very much in their degree of violence, and in their depth and extent; and they are much more common in young healthy persons than in others.

WHIT'SUNTIDE, the seventh Sunday or forty-ninth day after Easter, and properly called *Pentecost*. It is said to have received its popular name from the circumstance that, formerly, those who were baptized that day were dressed in white for the occasion.

WHOOPING COUGH, CHINCOUGH, or KINCOUGH, a convulsive cough, accompanied by a whooping inspiration, and having its paroxysms generally terminated by expectorations of mucus, or vomiting. It is infectious, usually attacks children, and affects the same person but once. It generally begins with slight febrile symptoms, and a common cough, which in about a fortnight becomes spasmodic; it ordinarily lasts for some weeks. When the head is much affected, or it is accompanied by bronchitis, it is dangerous. It is commonly followed by relics, which are best removed by change of air.

WHORTLEBERRY, the fruit of a shrubby alpine plant, belonging to the genus *Vaccinium*, which also includes the cranberry, bilberry, and cowberry plants, nat ord *Vacciniaceæ*.

WICK'LIFFITES, called also *Lollards* [which see], a religious sect which sprung up in England in the reign of Edward III., and took its name from John Wickliffe, doctor and professor of divinity in the university of Oxford; who maintained that the substance of the sacramental bread and wine remained unaltered after consecration; and opposed the doctrine of purgatory, indulgences, auricular confession, the invocation of saints, and the worship of images He made an English version of the Bible; and composed two volumes called *Aletheia*, that is Truth: from which John Huss learned most of his doctrines. They were the precursors of the reformation, which took place about two hundred years after.

WIG'WAM, a name given by the English to the huts or cabins of the North American Indians.

WILL (*willa: Sax*), that faculty of the mind by which we determine either to do or forbear an action. The will is directed or influenced by the judgment. The understanding or reason compares different objects, which operate as motives, the judgment determines which is preferable; and the *will* decides which to pursue.

WILL or TES'TAMENT, the disposition of a person's estate, to take effect after his or her decease. All wills made in England must be in *writing*, and each must be signed at the bottom or end by the testator, or, if he is unable, by some person by his direction, and in his presence; and two or more attesting witnesses (who must be present at the same time), must also sign the will in the presence of the testator. If the latter wishes to acknowledge or reward the attesting witnesses he must do it in some other way than by bequeathing them anything; for legacies to attesting witnesses, or to the wife or husband of an attesting witness, are void. The wills of soldiers and seamen, including officers, if regarding *personal estate*, need not be in writing. No person under twenty-one can make a valid will. Wills are revoked by subsequent marriage, by destruction, or by the making of a new one; and alterations in wills must be made in the same manner as a will. Wills are to be construed as if made immediately before the death of the testator, unless a contrary intention is expressed; and properties bequeathed in general terms include all property in the possession of the testator at his decease, whether acquired before or after the will was made. A married woman cannot make a will except as regards settled estate, and under a power given to her by the settlement *Codicils* are additions to a will, and require to be executed like a will.

WIL'LOW (*welig: A.-Sax.*), the name of trees belonging to the genus *Salix*, of which we have several species in Britain. Their twigs are employed under the name of osiers in basket making ——The *weeping willow*, *Salix Babylonica*, has long and slender branches, which droop and hang downward in graceful tresses. The willow was, in ancient days, especially among herdsmen and rustics, *a badge of mourning*, as may be collected from Virgil, in his Eclogues, where the nymphs and herdsmen are frequently introduced, sitting under a willow mourning their loves. The same occurs in many Greek poets For the ancients frequently selected, and, as it were, appropriated several trees, as indexes or testimonials of the various passions of mankind The Jews, upon their being led into captivity (Ps. cxxxvii), are said to hang their harps upon *willows*, *i e* trees appropriated to men in affliction and sorrow, who had lost their beloved Sion

WIL'LOW-HERB, the common name of plants belonging to the genus *Epilobium* Several species are wild in Britain, and others are cultivated in gardens, but none are of any use.

WINCHESTER BUSHEL, the original English standard measure of capacity given by King Edgar, and kept in the town-hall of the ancient city of Winchester, with other measures both of quantity and length Until the year 1826, when the imperial standard measure was introduced, the Winchester bushel was the standard for England.

WIND, a motion or sensible current of the air. As it is a fluid, the natural state of air is rest, which it always endeavours to preserve, and if disturbed to recover. When, therefore, this equilibrium is destroyed by rarefaction in particular places, the weightier air will rush in to restore it; the resulting currents being often deflected by mountains and crossed by other currents. The different degrees of rarefaction by day, and condensation by night, keep the air in a state of constant activity The rare superior parts appear, however, to be more affected than the lower stratum, balloons having been carried upwards of sixty miles an hour, at the height of two miles, while the moderate wind below has not moved more than fifteen miles. In different countries the direction of the winds differs considerably, according to the situation of the places where the observations have been made. In Great Britain the south-west is by far the most frequent wind. In April, May, and part of June, the east wind is common, especially on the east coast of the island. In Ireland the south-west and west are the most prevalent. On the south coast of Europe the most frequent winds are the north, the north-east, and the north-west; and on the western coast the north-west prevails. [See TRADE WINDS, ATMOSPHERE, &c.]

WIND'AGE, the difference between the bore of a gun and the diameter of the ball; it has been latterly much diminished, the result of which is that the ball will go much more truly, and less powder is required. It was formerly one-twentieth of the diameter of the bore.

WIND'BOUND, an epithet for a ship that cannot leave the port on account of unfavourable winds.

WIND'LASS (*windam*, to turn round: *Sax.*), a common mechanical contrivance, by which weights are raised, water drawn out of a well, &c. Since the momentum is in proportion to velocity, and the hand at the winch makes a larger circle than the cylinder round which the rope coils, the power is rendered very effective by this machine. For, if the hand describes a circle of six feet, while the bucket, &c. moves through but one foot, the power of the hand, friction not being taken into account, is capable of overcoming six times its amount at the bucket, &c.

WIND'MILL, a machine erected in elevated positions, and provided with vanes or sails, which are so placed as to be turned by the wind. In order that the wind may regulate the position of the mill, a vane is placed on the side which is opposite the sails, and by a simple mechanism turns them always to the wind. When the mill is not too large it is either turned round on a vertical axis, with a lever, or the roof alone with the axle and wings is moved. In the former case it is called a German mill, in the latter a Dutch mill. On account of the inconstant nature of the wind, it is necessary to have some provision for accommodating the resistance of the sails to the degree of violence with which the wind blows. This is generally done by clothing and unclothing them; that is, by covering, with canvass or thin boards, a greater or smaller portion of the frame of the sails, according to the force of the wind at different times. A method has been devised for producing the same effect, by altering the obliquity of the sails; and windmills have been so made as to regulate their own adjustment. A horizontal arrangement of the sails has been frequently tried, but it has never been found to answer. The moving force being very irregular and entirely interrupted in calm weather, windmills are applicable only in particular cases; they are used in Holland very advantageously for drainage. The angle which the sails should make with the plane of the arms has been the subject of much investigation.

WINE, a liquor drawn from vegetable bodies, and fermented; but more especially, the fermented juice of the fruit of the vine. *Wine* differs essentially from *spirit*, the former being only *fermented*, and the latter also *distilled*. From the definition here given, it will be evident that ale, cider, and other vegetable fermented liquors, are properly wines; though the term is, by custom, confined to liquors drawn from the grape. Wines are divided into two principal classes; *red* and *white*. *White wines* are of an amber colour, more or less deep; but so called to distinguish them from the *red* wines. The generality of white wines are made from white grapes; but some are from black ones, the skins of which are carefully kept from imparting their colour. On a chemical investigation, all wines consist chiefly of water and alcohol, besides some vegetable acid, the carbonic acid, tartar, and an astringent gum-resinous matter, in which the colour of the red wine resides, and which is expressed from the husks of the grape. They differ from each other in the proportion they contain of these ingredients, and particularly of the alcohol; some of the latter, called *vinage*, is added, in many districts, to render the wine capable of removal for exportation. In a very hot country the grape becomes too saccharine; in one that is too cold it does not ripen sufficiently. The seeds of the grape, which contain tannin and extractive matter, modify the taste of wine; they are added in making port wine, but generally are excluded from the wines of Bordeaux and the Rhine. The *aroma* of wine is often factitious, being produced by aromatic herbs, &c. When it can be relied on, however, it is a test of excellence; it is distinct from *flavour*. The quality of wine depends very much upon the circumstances attending the process of fermentation. The general effects of wine are, to stimulate the stomach, exhilarate the spirits, quicken the circulation, promote perspiration, and, when taken in large quantities, to prove intoxicating, and powerfully sedative. Among the Greeks and Romans, the sweet wines were those most commonly in use; and, in preparing their wines, the ancients often inspissated them until they became of the consistency of honey, or even thicker. They were diluted with water previously to being drunk; and indeed, the habit of mixing wine with water seems to have prevailed much more in antiquity than in modern times. In 1865 we imported 2,204,580 gals. of wine, of which about one-half came from Spain, one-fifth from Portugal, and one-sixth from France.

WING (*gehwing: Sax.*), the limb of a bird admirably constructed and covered with feathers for the purpose of aerial locomotion. The different bones of the wing are bound together, and connected with the bones of the body by strong ligaments; and the muscles by which motion is communicated to them are the most powerful with which a bird is provided.——The wings of insects are highly varied, often very beautiful, and so important that their different characteristics give rise to the division of insects into Coleoptera, Hymenoptera, Diptera, Neuroptera, &c. [see these terms]. ——*Wing*, in Architecture, a side building, less than the main edifice. In Botany, the side petal of a papilionaceous corolla. ——*Wings*, in Fortification, the longer sides of horn-works, crown-works, tenailles, and other outworks; including the ramparts and parapets, with which they are bounded on the right and left from their gorge to their front.——*Wings*, in Military affairs, the two flanks or extremes of an army, ranged in order of battle.——In Naval constructions, passages along the sides of the ship, between the fore and after cockpit.

WING'ED, in Botany, a term applied to such stems of plants as are furnished with a prolongation of the leaves in the shape of a wing; as in some of the thistles. *Winged leaves* are such as consist of several little leaves ranged in the same direction, so as to appear only as the same leaf. Such are the leaves of agrimony, acacia, ash, &c. *Winged seeds* are such as have down or hairs, called *pappus* by botanists, by means of which the wind carries them to a distance.

WIN'TER (*Ang.-Sax.*), one of the four seasons of the year; commencing on the day when the sun's distance from the zenith of the place is the greatest, and ending on that when it is at a mean between the greatest and the least. The sun is nearer to the earth in winter than in summer; the coldness of winter is therefore owing to the shortness of the days or time during which the sun is above the horizon; and the oblique direction in which his rays fall upon our part of the globe at that season.

WINTER-CHERRY, a plant of the genus *Physalis*, and its fruit, which is of the size of a cherry. It is sometimes called the Cape gooseberry.

WI'RE-DRAWING, a very curious art, by which with the aid of steam, water, or some other power, wire is drawn through orifices successively smaller. Wire may thus be reduced from an inch to the 1000th of an inch in diameter, and gold has been made the 4000th of an inch in diameter. A single grain of gold admits of being drawn out easily into a wire 100 yards long. That property of metals by which they submit to this operation without breaking is called their *ductility*, which see.

WI'RE-WORM, the larva of a beetle belonging to the genus *Elater*, which is very destructive to wheat. It is computed that the crops on 60,000 acres are annually destroyed by this insect in Great Britain.

WIS'DOM OF SOLOMON, one of the books of the Apocrypha. It is by many thought to have been written after the cabalistic philosophy was introduced among the Jews.

WIT (*witam*, to know: *Sax.*), in its original signification, was synonymous with wisdom. Thus we read of our ancient wittenagemot, or Saxon parliament, an assembly of wise men; and so late as the Elizabethan age, a man of great or pregnant wit meant a man of vast judgment. The word wit, however, like many others, has in the course of time undergone various mutations. According to Locke, wit lies in the assemblage of ideas, and putting those together with quickness and variety, so that a congruity of associations and pleasant images may be present to the fancy; while Pope defines it to be a quick conception and an easy delivery. It is evident that wit excites in the mind an agreeable surprise; and that this is entirely owing to the strange assemblage of congruous ideas presented to the mind. Of so much consequence are surprise and novelty, that nothing is more vapid than a joke that has become stale by frequent repetition. For the same reason a witty repartee is infinitely more pleasing than a witty attack; and a pun or happy allusion thrown out extempore, in conversation, will often appear excellent, though it might be deemed execrable in print. As a learned divine has well observed: 'Sometimes it playeth in words and phrases, taking advantage from the ambiguity of their sense, or the affinity of their sound; sometimes it is wrapped in a dress of humorous expression; sometimes it lurketh under an odd similitude; sometimes it is lodged in a sly question, in a smart answer, in a quirkish reason, in a shrewd intimation, in cunningly diverting or cleverly retorting an objection; sometimes it is couched in a bold scheme of speech, in a tart irony, in a lusty hyperbole, in a startling metaphor, in a plausible reconciling of contradictions, or in acute nonsense. Often it consisteth in one knows not what, and springeth up one can hardly tell how.'

WITCH'CRAFT (*wicce*, a witch: *Sax.*), a supernatural power, which persons were formerly supposed to obtain by entering into compact with the evil one. It was believed that they gave themselves up to him body and soul; and he engaged that they should want for nothing, and should be able to assume whatever shape they pleased, to visit and torment their enemies! A belief in witchcraft was prevalent among the Greeks and Romans; but it was founded on incantations and magical practices. There is only one particular narrative of a witch, in the Old Testament, the evocation of Samuel by the witch of Endor. Witchcraft was universally believed in throughout Europe till the 16th century; and it even maintained its ground with tolerable firmness till the 17th. Vast numbers of reputed witches were convicted and condemned to be burnt. It is recorded that 500 witches were burnt at Geneva in three months, about the year 1515; that 1000 were executed in one year in the diocese of Como; and it has been calculated that not less than 100,000 victims must have suffered, in Germany alone, from the date of Innocent's bull, in 1484, which directed the Inquisition to be vigilant in searching out and punishing witches, to the final extinction of such prosecutions. The number of those put to death in England has been estimated at about 30,000.

WITENAG'EMOTE (an assembly of wise men: *Sax.*), the great national council of the Anglo-Saxon kings. It consisted of bishops, abbots, earls, aldermen, thanes of

Danish burghs, and, it is supposed, of all who possessed forty hides of land.

WITH'ERITE, in Mineralogy, a carbonate of barytes. It is grey, white, or yellow.

WITNESS, in Law, one who gives evidence in legal investigations. In civil cases, witnesses are compelled to appear by *subpœna* [which see]; and if they neglect to attend are punishable by attachment or action. In criminal cases, by *subpœna* or *recognizance*, taken by the magistrate before whom the information is given. Persons are incompetent according to law to give evidence in a court of justice if they want reason, or do not believe in the existence of a God and the rewards and punishments of a future state.

WOAD (*wad: Sax.*), a cruciferous plant of the genus *Isatis*, from which is extracted a drug that imparts a blue colour, and is much used by dyers. It springs from seeds annually sown in the spring; and is grown in France and on the coasts of the Baltic. ——The ancient Britons are said to have painted their bodies with the dye procured from this plant.

WODEN, an Anglo-Saxon deity supposed to correspond with Mercury, and erroneously believed by some to be the same as Odin. He has given its name to Wednesday.

WOLF (*walf: Sax*), the *Canis lupus*, a ferocious quadruped, in habits and physical development closely allied to the dog. It is very destructive to sheep; and, when pressed with hunger, will enter houses and even devour children. The wolf was at one time a native of this country, and all possible means were adopted to rid it of so rapacious a despoiler. King Edgar attempted to effect this, in England, by remitting the punishment of certain crimes on producing a certain number of wolves' tongues; and in Wales, the tax of gold and silver was commuted for an annual tribute of their heads. They were so numerous in Scotland, about the middle of the 15th century, that they completely overran the country, to the destruction of the flocks; nor were they, with every exertion of the natives, totally extirpated till the year 1680, when the last wolf is recorded to have fallen by the hand of the famous Sir Ewen Cameron.

WOLF'-FISH, the *Anarrhicas lupus* of ichthyologists, a fierce and voracious fish of the northern seas; sometimes taken on our coasts, and attaining to the length of six feet. It has a cat-like face, and its teeth are strong and pointed.

WOL'FRAM, in Mineralogy, is the native tungstate of iron and manganese, which occurs in primitive formations, along with the ores of tin, antimony, and lead, in North America, Bohemia, Switzerland, Cornwall, &c. Tungsten, which is sometimes termed wolframium, and tungstic acid, are obtained from it.

WOL'VERENE. [See GLUTTON.]

WOM'AN, the female of the human race, grown to an adult age. Among the Greeks and Romans, women were employed in spinning, weaving, embroidery, and all sorts of needle-work; their education being wholly confined to their domestic duties. 'In every age and country (says Gibbon), the wiser, or at least the stronger, of the two sexes has usurped the powers of the state, and confined the other to the cares and pleasures of domestic life. In hereditary monarchies, however, and especially in those of modern Europe, the gallant spirit of chivalry, and the law of succession, have accustomed us to allow a singular exception; and a woman is often acknowledged the absolute sovereign of a great kingdom, in which she would be deemed incapable of exercising the smallest employment, civil or military. But as the Roman emperors were still considered as the generals and magistrates of the republic, their wives, although distinguished by the name of Augusta, were never associated to their personal honours; and a female reign would have appeared an inexpiable prodigy in the eyes of those primitive Romans who married without love, or loved without delicacy and respect.' In our treatment of the sex there is a just medium to be observed—as far removed from their humiliation as it is from that extravagant homage which stops at nothing short of their deification. Woman is the equal and companion of man—not the plaything of his caprice, nor the slave of his passions.

WON'DER, that emotion which is excited by something presented to the senses which is either sudden, extraordinary, or not well understood. The word *wonder* is nearly allied to *astonishment*, though it expresses less, and much less than *amazement*.——Among the Ancients, *the seven wonders of the world* were—the Egyptian pyramids—the mausoleum erected by Artemisia—the temple of Diana at Ephesus—the walls and hanging gardens of Babylon—the colossus at Rhodes—the statue of Jupiter Olympus—and the Pharos or watch-tower at Alexandria.

WOOD (*wude: Sax.*), in Plants, the support of all the deciduous organs of aeration, assimilation, and fructification; the deposit of the secretions peculiar to the individual species; the reservoirs whence the newly formed parts derive their sustenance, until they can establish a communication with the soil. It consists of *woody tissue*, and various kinds of vessels surrounded by *cellular matter*. While young it is succulent and brittle, and nearly the same in all plants, but it becomes hard as it grows old, by the addition of secondary deposits within the woody tissue. While young it is called *sapwood* or *alburnum;* when hardened and coloured, it is *heartwood* or *duramen*. It contains a large quantity of nitrogen, which causes it to be perishable, but which may be removed by washing; and its azotized matter is believed to be rendered insoluble by certain preservative agents. The concentric circles of the wood determine the age of the tree.

WOOD'COCK, the *Scolopax rusticola*, a bird allied to the snipe, much prized by epicures, inhabiting the northern parts of the European continent in summer, but frequenting England in winter.

WOOD-ENGRAVING, or wood-cutting, the art of cutting figures in wood, that they may be printed by the same process as common letter-press. The mode of engraving on wood is exactly the reverse of that of copper-plate, the parts intended to appear being raised on the surface. The wood which is used for the purpose of engraving is that of the box-tree, of which a considerable quantity is imported from Turkey. The design drawn upon the wood is the reverse of the object copied, so that when the impression is taken from the engraving the object is correctly represented. [See ENGRAVING.]

WOOD'-GELD, in our ancient customs, the gathering or cutting of wood within the forest; or the money paid for the same to the foresters. Sometimes it also seems to signify an immunity from this payment by the king's grant.

WOOD'PECKER, a name given to some scansorial birds forming the genus *Picus* of ornithologists. Four species are known in Britain, of which the green woodpecker, *Picus viridis*, is the commonest. They climb trees in search of larvæ, and are able to ascend a trunk with facility by means of their strong claws, and the support derived from propping themselves with their tail feathers.

WOOD'-PIGEON, or RING DOVE, the *Columba palumbus* of ornithologists. [See PIGEON.]

WOODY FIBRE. [See LIGNINE.]

WOOF, the cross threads in weaving, introduced by the shuttle, when part of the warp is raised.

WOOL (*wul: A.-Sax.*), the fleecy coat of the sheep, which in fineness sometimes approaches fur. Wool, like the hair of horses, cattle, and most animals, completes its growth in a year, then falls off as hair does, and is succeeded by a fresh crop. It differs from hair, however, in the uniformity of its growth and the regularity of its shedding. Hairs are commonly of the same thickness in every part; but wool constantly varies in thickness in different parts, being generally thicker at the points than at the roots. While the wool yet remains in the state it was first shorn off the sheep's back, and before being sorted into its different kinds, it is called a *fleece*. The wool of the same animal differs much on the various parts of the body, that on the back and the sides being the best. The great difference in the wool of different sheep depends, in general, upon their descent, the crossing of breeds, climate, food, age, and manner of living. Some of the most scientific 'wool-growers' maintain, that the degree of softness (the most valuable quality in wool) depends principally on the nature of the soil on which sheep are fed; that sheep pastured on chalky districts, or light calcareous soil, usually produce hard wool; while the wool of those that are pastured on rich, loamy, argillaceous soils, is always distinguished by its superior softness. Wool, either in a raw or a manufactured state, has always been the principal of the staple articles of this country. Before the time of Edward III. it was always exported raw, the art of working it into cloth and dyeing being so imperfectly known that no persons above the degree of working people would dress in cloth of English manufacture. The first step taken to encourage the manufacture of woollen cloths was by Edward III., who procured some good workmen from the Netherlands, by means of protection and encouragement. The value of wool was considered so essentially solid, that taxes were vested in that commodity, reckoning by the number of sacks; and in proportion to the price of the necessaries of life, and value of silver, wool was at least three times dearer than it is now. By an act of Henry IV. c. 2, the exportation of sheep, lambs, or rams was forbidden, under very heavy penalties. From 1660 down to 1825 the export of wool was strictly prohibited, but in the latter year the prohibition was removed. Wool in the state in which it is taken from the sheep is always mixed with much dirt and foulness of different kinds; and, in particular, is imbued with a peculiar potash soap, secreted in large quantity by the animal. These impurities are got rid of by washing, fulling, and combing, by which the wool is rendered remarkably white, soft, clean, light, and springy under the hand. When boiled in water for several hours, in a common vessel, wool is not in any way altered in weight and texture, nor does the water acquire any sensible impregnation The filaments of the finer wool vary from the one-thousandth to the one-fifteen hundredth of an inch in thickness; each filament of wool consists of a series of serrated rings. [See FELTING.] Besides the wool produced in this country, 209,394,249lbs. were imported in 1865, of which rather more than one-half came from Australia, and rather more than one-eighth from our South African colonies.

WOOL'LEN MAN'UFACTURE. There are two sorts of wool which afford the basis of different fabrics, the *long* wool, in which the fibres are rendered parallel by the process of combing; and the *short* wool, prepared by carding, like cotton, which is used in different degrees of fineness, for broad-cloths, flannels, &c. The wool of which good broad-cloth is made should be not only shorter, but, generally speaking, finer and softer than the worsted wools, in order to fit them for the fulling process. The best English short native fleeces, such as the fine Norfolk and Southdown, are generally divided by the wool-sorter into several kinds: all varying in fineness. When the wool is dyed, the cloth is said to be *wool dyed;* but when the cloth itself is dyed, it is said to be *piece dyed.* In cloths made of short wool, the web, when taken from the loom, is loose and open, and requires to be submitted to the operation of *fulling*, by which the fibres are made to *felt*, and combine more closely. By this process the cloth is reduced in its dimensions, and the beauty and stability of the texture are greatly improved. The nap or downy surface of broad-cloths is raised by a process which, while it improves the beauty, tends somewhat to diminish the strength of the texture. It is produced by carding the cloth with heads of teasel (*Dipsacus fullonum*), a plant cultivated for the purpose. This operation extricates a part of the fibres, and lays them in a parallel direction. The nap, composed of these fibres, is then cut off to an even surface, by the process of *shearing*. This is performed in various ways; but, in one of the most common methods, a large spiral blade revolves rapidly in contact with another blade, while the cloth is stretched over a bed, or support, just near enough for the projecting filaments to be cut off at a uniform length, while the main texture remains uninjured. *Pressing* finishes the cloth, and gives it a smooth level surface. The piece is folded backwards and forwards in yard lengths, so as to form a thick package on the board of a screw or hydraulic press. Between every fold sheets of glazed paper are placed, to prevent the contiguous surfaces of cloth from coming into contact; and with the assistance of hot iron plates, carefully arranged, and severe compression, the cloth receives a smooth and glossy appearance. The value of the manufactured wool, imported into this country, in 1865, amounted to 1,704,758*l*., but this did not include 4,392,090lbs. of woollen and worsted yarn. The total declared value of woollen and worsted manufactures exported from the United Kingdom in 1865 was 20,102,259*l*.

WOOL'SACK, a name for the seat of the lord chancellor in the House of Lords. It is so called, from being a large square bag of wool, without back or arms, covered with red cloth; it was adopted as a mark of the importance of our woollen manufacture. When, in the reign of Elizabeth, an Act of Parliament was passed to prevent the exportation of wool, to keep in mind this source of our national wealth, wool sacks were placed in the House of Lords for the lord chancellors, judges, and sergeants.

WOOTZ, steel imported from Bengal; it is excellent for cutting instruments, and is believed to contain minute portions of silica and alumina.

WORDS are signs, or symbols of ideas and thoughts, produced by sounds, and combinations of sounds, or by letters and their combinations. [See LANGUAGE.]

WORM (*wyrm: Sax.*), in a popular sense, any small cylindrical animal, or reptile, including a great variety of different classes and orders.——*Worm*, in Laboratories and Distilleries, a spiral pipe almost always of metal, placed in a vessel of water. The vapour formed during the process of distillation, being transmitted through it, is cooled and condensed. As the water by which it is surrounded becomes hot it ascends and flows away, its place being supplied by a fresh portion, which enters below.——In Gunnery, a screw of iron, which may be fixed on the end of a rammer, to pull out the wad of a cannon, firelock, or pistol.

WORM'ING, an operation performed on puppies, under an ignorant supposition that it prevents them going mad; but in reality to cure them, as it generally does, of the disposition to knaw everything in their way. It consists in the removal of a small worm-like ligament, situated beneath the tongue; and the part being afterwards sore for some days, the animal is thus weaned of his mischievous habits.

WORM'WOOD, a small composite shrub, the *Artemisia absinthium* of botanists, formerly used in medicine as a tonic and anthelmintic. The seed is employed by the rectifiers of British spirits, and the plant is a good deal cultivated in certain parts of England for that purpose.

WOR'STED (*Worsted*, a town in Norfolk, famous for the woollen manufacture), a kind of thread or yarn spun of wool that has been combed, and which, in the spinning, is twisted harder than ordinary. It is chiefly used either to be knit or woven into stockings, caps, &c.

WOULFE'S APPARA'TUS, a very useful apparatus for chemical purposes, consisting essentially of one or more bottles, each having two or three necks; and is used for impregnating water and other fluids with vapours and gases. Before it was known, the only vessels that chemists employed for distillations were either the alembic with its refrigeratory, or the retort with its receiver. The former was devoted almost exclusively to the distillation of those fluids which are readily condensed by cooling, and are not attended with the production of much permanently elastic vapour, or such as was not easily condensable: thus, water impregnated with the aromatic parts of vegetables, alcohol, &c.; whilst the retort, with its glass receiver, was reserved for the distillation of the stronger acids, and other substances accompanied by much uncondensable vapour. In experiments of research, the old apparatus was peculiarly defective, as the gaseous products, which are often by far the most interesting, were entirely lost. When Woulfe's apparatus is employed, a retort or other vessel, for heating the materials, is connected by means of a bent tube with one of Woulfe's bottles. If more than one of these bottles are required they are ranged side by side, and are connected with each other by tubes, each of which proceeds from the upper part of one bottle to the bottom of the liquid in the next, the centre neck of each bottle, if it have three necks, being closed either with a solid cork, and if necessary luted, or with a cork in which is inserted a *safety-tube*, that passes down through it, and dips in the liquid at the bottom. This tube allows the elastic fluid, if generated in too large quantity, to escape into the atmosphere; while, in ordinary circumstances, as it dips into a liquid, they are unable to pass off. Every part of the apparatus is air-tight, except the extremity farthest from the retort, so that every particle of vapour or gas has to traverse the whole series of vessels, and to pass through the liquid in every one of the bottles, before it escapes into the air; and thus, if at all condensable by the liquid used, can hardly escape condensation. The apparatus was not altogether unknown, even before Woulfe's time

WOU'RALI PORSON. [See URALI.]

WRACK, in Botany, the *Fucus vesiculosus*, a marine plant which is of great utility as a manure. It is found on rocks left dry at low water; the stalk runs along the middle of the leaf, and is terminated by watery bladders. It is sometimes called *sea-oak* and *sea-tangle*.

WRAN'GLER, SENIOR, in the university of Cambridge, the student who passes the best examination (especially in mathematics) in the senate-house, for the first degree, or that of bachelor in arts; they who follow next in the same division are respectively termed *second*, *third*, *fourth*, &c., *wranglers*. The students belonging to the next two classes are termed senior, and junior *optimes*, respectively; and the fourth or lowest class consists of the *hoi polloi* (the many).

WRASS, or **WRASSE**, a name given to marine fishes belonging to the spiny finned genus *Labrus*.

WRECK (*wracke: Belg.*), in Navigation, the destruction of a ship, by being driven ashore. Also, a vessel found floating at sea in a deserted and unmanageable condition. But in order to constitute a legal wreck, the goods must come to land. In former times the most inhospitable and barbarous conduct was exercised against all who had the misfortune to suffer from the perils of the sea; but as commerce and navigation were extended, the law was made to afford the adventurous mariner protection. In England, as in other countries, wrecks had been adjudged to the king; but the rigour and injustice of this law was modified so early as the reign of Henry I.; when it was ruled, that if any person escaped alive out of the ship, it should be no wreck. And after various modifications, it was decided, in the reign of Henry III., that if goods were cast on shore, having any marks by which they could be identified, they were to revert to the owners, if claimed any time within a year and a day. The plundering of wrecks had, however, become so confirmed by the custom of ages, that various subsequent penal statutes were enacted to repress it; even so lately as the reign of George II. it was found necessary to pass a new statute for the purpose; and by a statute of George IV., plundering wrecked vessels or goods stranded is felony; goods cast overboard and not stranded are divided into *jetsam*, or those sunk to the bottom; *flotsam*, or things found floating; and *ligsam*, or things sunk, but attached to a buoy or cork, that they may be found again; all these belong to the crown if no owner appears to claim them. Insurance against loss by wreck is effected with persons called underwriters, who chiefly exercise their calling at Lloyd's, in the Royal Exchange, London.

WREN (*wrenna: Ang.-Sax.*), the name of small birds belonging to the genus *Troglodytes*. The common wren (*T. vulgaris*) is the chesnut coloured, with the wings variegated with white and grey. This is a minute bird, and, except the golden-crowned wren, the smallest of any in Europe; the head is large and round, the eyes dark, and the beak slender and brown; the tail is short, and generally carried erect; the head, neck, and back, are of a dusky chesnut-brown; the breast is of a dusky white, and the lower part of it is variegated with obscure and transverse lines of black. It is fond of prying about crevices and holes in walls, and is constantly in motion, searching for insects, which form its principal food.——The *golden-crowned wren* is distinguished by an orange crown; its length is 4½ inches, and its weight under 80 grains. It builds its nest, which is remarkably neat, on the oak, yew, or some species of the pine. This is most commonly open at the top, but sometimes covered with a dome, and it has an opening on one side. It is always ingeniously suspended beneath the branch, like those of many tropical birds, being the only instance of the kind amongst those of Great Britain. The eggs are about ten in number, and are small, round, and white. In a still and sultry noon, when not a leaf is stirring, and almost every other bird has retired from the heat of the sun into the shadiest thickets, the little solitary golden-crowned wren is to be seen flitting noiselessly from spray to spray, in search of its food, paying no attention to any one who happens to be watching it; and never for a moment remaining in a state of rest. The lightness and airiness of its motions, as it hops and flutters about upon the smallest twigs, are unrivalled; and in shape and plumage it is also superior to most of the feathered inhabitants of our groves and gardens. Its song is very soft and low—a mere whisper—and therefore quite in keeping with its tiny and delicate form.

WREST'LING (*wræstan*, to twist by violence: *Sax.*), a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent on the ground. Wrestling is an exercise of very great antiquity and fame. It was in use in the heroic age; and had considerable rewards and honours assigned to it at the Olympic games. The wrestlers of Cornwall and Devon in the south-west, and Cumberland and Westmorland in the north-west, seem to have always been most celebrated among the English athletæ.

WRIST (*wyrst: Sax.*), in Anatomy, the *Carpus*, that joint by which the hand is united to the arm. It is composed of eight small bones in two rows, the motions of which on the fore-arm may be described as those of flexion, extension, abduction, and circumduction.——In the manege the *bridle wrist* is that of the left-hand. A horseman's wrist and his elbow should be equally raised; and the wrist should be two or three fingers above the pommel of the saddle.

WRIT, in Law, a precept in writing, under seal, issued by some court or magistrate in the name of the government, and addressed to a sheriff, his deputy, or other subordinate executive officer, commanding him to do some particular thing. Writs have been much reduced in number; the *original* writ, issuing out of chancery, for the commencement of actions in the three courts of common law, is now superseded by three *judicial* writs, which issue in the name of the chief justice of the respective courts; these are the writ of *summons*, the writ of *capias ad respondendum*, and the writ of *detainer*. The first is ordinarily used; the second only when it is intended to arrest the defendant; and the third, when he is already in prison for some other cause. A writ, or summons, is called a *subpœna*, when it requires witnesses to appear to give evidence of *habeas corpus*, when it is to bring up the body; of *premunire*, when it incurs forfeiture of all property; and of *qui tam*, when to recover a fine, of which the prosecutor is to have a share. These and others will be found in their respective places in this work.

WRITER *to the Signet*, a numerous society of lawyers, in Scotland, equivalent to the class of attorneys and solicitors in England.——*Writer of the Tallies*, formerly an officer of the English exchequer; a clerk to the auditor of the receipt, who wrote upon the tallies the whole of the tellers' bills. [See TALLIES.]

WRI'TING (*writan*, to write: *Sax.*), the art and act of expressing ideas by letters or characters visible to the eye. Without its aid the experience of each generation would have been almost entirely lost to succeeding ages, and only a faint glimmer of truth could have been discerned through the mists of tradition. The most ancient remains of writing, which have been transmitted to us, are upon hard substances, such as stones and metals, which were used for edicts and matters of public notoriety. Thus we read that the decalogue was written on two tables of stone; but this practice was not peculiar to the Jews, for it was used by most of the Eastern nations as well as by the Greeks and Romans. The laws, penal, civil, and ceremonial, among the Greeks were graven on tables of brass, called *kurbeis*. The Chinese, before the invention of paper, wrote or engraved with an iron tool, or style, upon thin boards or on bamboo. Pliny says, that table-books of wood were in use before the time of Homer; afterwards these were usually waxed over, and written upon with a style the writing was then easily effaced, and by smoothing the wax, new matter might be substituted in the place of what was written before. The bark of trees was also used for writing by the ancients, and is so still in several parts of Asia. The same may be said of the leaves of trees. But the Greeks and Romans continued the use of waxed table-books long after the use of papyrus, leaves, and skins became common, because they were so convenient for correcting extemporary compositions. [See PAPER, PAPYRUS, &c.]——Where writings have been effaced for fraudulent purposes with muriatic acid, sulphuret of ammonia and prussiate of potash will revive them. Very old writing may be revived in this way. If indigo and oxide of manganese be added to common ink, it will prevent its being effaced by muriatic acid.

WRYNECK. [See YUNX.]

WYV'ERN, in Heraldry, a kind of flying serpent, an imaginary animal, occasionally represented in coats of arms.

X

X, the twenty-fourth letter of the English alphabet, is borrowed from the Greek. When used at the beginning of a word, it has precisely the sound of *z*; but in the middle and at the end of words, its sound is the same as *ks*—as *wax*, *luxury*, *taxation*, &c. In French it is variously pronounced. It is not found in Italian, its place being supplied by *ss*, as in *Alessandro;* the Germans generally substitute for it *ks*, *gs*, or *chs*, and never use it in the beginning of a word. It begins no word in our language but such as are of Greek original, and is found in few others besides those which are of Latin derivation. As a numeral, X stands for ten. When laid horizontally, thus ⋈, it stands for a thousand, and with a dash over it, ten thousand. As an abbreviation, X stands for *Christ*, as in Xn, *Christian;* Xmas, *Christmas*.

XAN'THIAN MARBLES, a collection of sculptures in the British Museum, obtained chiefly from Xanthus in Lycia, Asia Minor. They range in date from the subjugation of the country by the Persians, B.C. 545, to the period of the Byzantine Empire. They were discovered by Sir C. Fellows, and brought to this country by two expeditions, sent out by the government in 1842-46.

XAN'THIC OXIDE (*xanthos*, yellow: *Gr.*), in Chemistry, a very rare species of urinary *calculus*, of a reddish or yellow colour, soluble both in acids and alkalis; and its solution in nitric acid, when evaporated, possesses a brilliant yellow tint: hence its name. It is composed of carbon, hydrogen, nitrogen, and oxygen.

XAN'THINE (same *deriv.*), the yellow colouring principle of madder.

XAN'THITE (same *deriv.*), a mineral found in small grains and crystals of a yellow colour, near New York; its principal constituents are silicate of lime and silicate of alumina.

XAN'THIUM (*xanthion*, from *same: Gr.*), in Botany, a genus of composite plants containing the *Lesser Burdock*, the *Xanthium Strumarium* of botanists. It was once esteemed for cases of scrofula, but, like most other remedies against this disease, proves ineffectual. It is sometimes used as a yellow dye; hence its name.

XAN'THOGEN (*xanthos*, yellow; and *gennao*, I produce: *Gr.*), in Chemistry, the base of an acid, obtained in combination with potash by the mixture of a solution of pure potassa with bisulphuret of carbon. It contains sulphur, carbon, and hydrogen, and obtained its name from the yellow colour of its compounds.

XANTHOX'YLUM (*xanthos*, yellow; and *xulon*, wood: *Gr.*—from its yellow hue), in Botany, a genus of trees growing in Asia and America, and including the Toothache-tree, so called from its supposed virtue in pains of the teeth. It belongs to the nat. ord. *Xanthoxylaceæ*, and is a native of America.

XEBEC', a small three-masted vessel, used in the Mediterranean Sea, and on the coasts of Spain, Portugal, and Barbary. Having been usually equipped as a corsair, the xebec is constructed with the *floor*, or part which touches the earth when it is aground, narrow, for the sake of speed; and of a great breadth, so as to be able to carry a considerable force of sail without danger of overturning. When close-hauled, it carries large lateen sails. The Algerine xebecs were usually equipped with from 16 to 24 guns, and from 300 to 450 men, two-thirds of whom were soldiers.

XENELA'SIA (*xenos*, a stranger; and *elausio*, I drive away: *Gr.*), in Antiquity, a law among the Spartans, by which strangers were excluded from their society; not out of fear lest they should imitate the Spartan manners, but lest the Spartans should be contaminated by foreign vices. It was a barrier set up against contagion; but was not so strict as to prevent deserving persons, or men of talent, from being received.

XE'NIA (*Gr.*; from *xenos*, a stranger), among the Greeks and Romans, presents made by strangers to such as had treated them with kindness and hospitality. *Xenia* was also a name given to the gifts and presents made to the governors of provinces by the inhabitants.

XERA'SIA (*xērasia*, from *xēros*, dry: *Gr.*), in Medicine, an excessive tenuity of the hairs. It is common among animals which are badly fed: the hairs resemble down and fall off through dryness, from want of proper nourishment. It is a species of *Alopecia*, which see.

XEROCOLLYR'IUM (*xērokollurion*, from *xēros*, dry; and *kollurion*, an eye-salve: *Gr.*), in Medicine, a dry collyrium or eye-salve.

XEROPH'AGY (*xērophagia*; from *xēros*, dry; and *phagein*, to eat: *Gr.*), the name given to a sort of fast which was adopted in the primitive ages of Christianity, and which consisted entirely of dry viands.

XEROPH'THALMY (*xērophthalmia*; from *xēros*, dry; and *ophthalmia*, a disease of the eyes: *Gr.*), in Medicine, a dry red soreness or itching of the eyes, without swelling or a discharge of humours.

XES'TES (*xestes*: *Gr.*), in Antiquity, an Athenian measure of capacity, answering to the Roman sextarius, and nearly to our pint.

XIPH'IAS (*Gr.*; from *xiphos*, a sword), in Ichthyology, a genus of fishes, including the common ***swordfish***, the ***Xiphias gladius***, which sometimes attains the length of 20 feet. The bones of the upper jaw project into a formidable weapon, the sword, which is flat above and below. It is an extremely rapacious fish, and finds in the above instrument a weapon of attack and destruction, able to procure it the most ample supplies. It is found in the Mediterranean, chiefly about Sicily, and is used by the inhabitants of that island for food. [See SWORDFISH.]

XI'PHOID (*xiphos*, a sword; and *eidos*, appearance: *Gr.*), a term given by Anatomists to parts which have some resemblance to an ancient sword; as the *xiphoid cartilage*, placed at the bottom of the breast-bone.

XYLAN'THRAX (*xulon*, wood; and *anthrax*, a coal: *Gr.*), in Mineralogy, *bovey-coal*. It consists of wood penetrated with petroleum or bitumen, and frequently contains pyrites, alum, sulphuric acid, &c.

XY'LO AL'OES (*xulon*, wood; and *aloē*, the aloe: *Gr.*), or *Aloewood*, in the Materia Medica, the product of the *Aquilaria Secundaria*, belonging to the *Aquilariaceæ*. It is the true aloewood, or *Calambac*, termed Agallochum, and must not be confounded with the *Aloexylon Agallochum*, of the nat. ord. *Leguminosæ*, which yields a scented wood used by the Chinese. It grows in China and some of the Indian islands. The Calambac is the most resinous of all the woods with which we are acquainted; it is of a light spongy texture, very porous; and its pores are so filled up with a soft and fragrant resin, that it yields to pressure like wax, or may be moulded by chewing in the mouth like mastich. Its scent, while in the mass, is very fragrant; and its taste acrid and rather bitter, but very aromatic and agreeable. It was formerly much esteemed in medicine, but is now little used.

XYLOG'RAPHY (*xulon*, wood; and *grapho*, I draw: *Gr.*), Wood engraving; the act or art of cutting figures in wood, in representation of natural objects. [See ENGRAVING.]

XY'LON (*xulon*, wood: *Gr.*), a species of punishment in use among the Greeks, which answered to our putting offenders in the pillory. It consisted in a heavy collar of wood, that prevented the delinquent from moving.

XYLOPHYL'LA (*xulon*, wood; and *phullon*, a leaf: *Gr.*—on account of the hardness and rigidity of its leaves), in Botany, a genus of plants, nat. ord. *Euphorbiaceæ*, the species of which produce their flowers at the edges of the leaves.

XYS'TARCH (*xustarchēs*; from *xustos*, the xystus; and *archo*, I govern: *Gr.*), an officer in the Grecian gymnasium, who presided over the *xystus*, as lieutenant to the gymnasiarch. His business was to superintend the *athletæ* in their exercises in the two *xysti*.

XYS'TER (*xuster*: *Gr.*), in Surgery, an instrument used for scraping bones.

XYS'TUS, or XYS'TOS (*xustos*, from *xuo*, I polish: *Gr.*—on account of its smooth and polished floor), in Ancient Architecture, an open or sometimes a covered court, of great length compared with its width, and consisting of porticoes with three sides. It was used for the performance of wrestling, running, &c., during the winter, and for walking in at other times. The Xystus made a necessary part of a gymnasium; and the name given to the athletæ who performed their exercises there was *Xystici*.

Y

Y, the twenty-fifth letter of the English alphabet. In the beginning of a word, it is considered to be a consonant; in every other position, a vowel. In the middle and at the end of words, *y* is precisely the same as *i*; being sounded as *i* long, when accented, as in *reply*, *defy*; and as *i* short, when unaccented, as in *synonymous*, *liberty*, *ability*, &c.——It was not introduced into the Latin alphabet till a late period; and was then confined to words borrowed from the Greeks, in which the Greek *υ* had been previously represented by the same letter instead of *y*. As a numeral it stands for 150 or, according to *Baronius*, for 159; and with a dash over it, for 150,000.

YACHT, a sailing vessel, pleasure-boat, or small ship with one deck, sufficiently large for a sea voyage. In its original signification, it is a vessel of state used to convey princes, ambassadors, and other great personages from one kingdom to another.

YAGERS (hunters: *Germ.*), higher servants, attached to aristocratic families in Germany. Also, light infantry armed with rifles, in Prussia, Austria, &c.

YAK, the *Bos grunniens* of naturalists, is an ox inhabiting the Himalayas. It has been domesticated, and is a very useful animal to the people of that mountainous region. It is employed as a beast of burden; its flesh is delicious, and its rich milk supplies them with much of their food. The long silky hair is spun into ropes, or woven into a material for tints. In appearance the yak resembles the bison; the usual colour is black, but white, red, and dun animals are common. They have large handsome eyes, spreading horns, and fine bushy tails. On the south side of the Himalayas the yak in winter feeds below 8,000 feet, but in summer it ascends as high as 17,000 feet. It emits a short grunt when excited, whence its specific name. The progenitor of this animal is the Wild Yak of Central Asia, which is untameable and very fierce.

YAM, a climbing plant belonging to the genus *Dioscorea*, cultivated in warm countries on account of its large farinaceous tuberous roots, which there form an important article of food when roasted or boiled. There are several species or varieties. The black bryony of our hedges belongs to an allied genus (*Tamus*), and its root also contains an edible fecula. The term yam is sometimes misapplied to plants belonging to the genus *Caladium* or *Colocasia*, also cultivated in warm countries on account of their edible tubers; these are the *taro* (or *kalo*) of the South Sea Islanders.

YAN'KEE, a popular name for a native of New England, but commonly applied to any inhabitant of the United States, as *John Bull* is to an Englishman, or *Mynheer* to a Dutchman. It is said to have originated in a corrupt pronunciation of the word *English* by the native Indians of America, who called the early settlers from Great Britain *Yengeese*.

YARD (*geard: Sax.*), a measure of three feet or thirty-six inches.——*Yards of a ship*, those long pieces of timber which are made a little tapering at each end, and are fitted each across its proper mast, with the sails made fast to them, so as to be hoisted or lowered as occasion serves. They have their names from the mast to which they belong. There are several sea-terms relating to the management of the yards: as, *square the yards*, that is, see that they hang horizontally, by the middle; *top the yards*, that is, make them stand even.——*Yard-arm* is that half of the yard which is on either side of the mast when the yard lies athwart the ship.——*Yard-arm and yard-arm*, a phrase applied to two ships when they are so near that their yard-arms nearly touch each other.

YARN (*gearn: Sax.*), primarily woollen thread; but it is applied also to other species of thread; thus to cotton and linen; and in rope making, to one of the hempen threads of which a rope is composed.

YAR'ROW, a well-known plant in our fields, belonging to the genus *Achillea* (nat. ord. *Compositæ*), and often called milfoil, or 'the plant of a thousand leaves,' from the excessive division of the foliage.

YAW, a sea-term, indicating temporary deviation from a direct course.

YAWS, in Medicine, the *Frambœsia* (*framboise*, a raspberry: *Fr.*), a severe cutaneous disease, introduced from Africa to the West Indies. It is said to derive its name from *yaw*, the African word for a raspberry. It affects a person but once, and is propagated solely by the infection of the matter of the pustules, applied to a part of the body where the skin is broken. It is not dangerous.

YEAR (*Sax.*), the period in which the revolution of the earth round the sun, and the accompanying changes in the order of nature, are completed. As regulated by the sun, it is called *solar*, and as regulated by the moon, *lunar*. The solar year is the interval of time in which the sun finishes his apparent course through the zodiac, and contains 365 days, 5 hours, 48 minutes and 49·7 seconds. The lunar year consisted of 12 lunar months. But besides the solar and lunar years, we may mention the *civil* year, which different nations adopted, without regard to *astronomical* accuracy, to render the computation of time in the common affairs of life more easy. The *Jewish* year consisted of 12 months, unless it happened to be intercalary, when it had 13 The ancient Hebrews used to regulate their months by the course of the sun, and each of them had 30 days; but after their captivity in Egypt, they adopted the lunar months, containing alternately 29 and 30 days, in all 354 days. This was made to agree with the solar year by adding eleven and sometimes twelve days at the end of the year, or by an *embolismic* month They had an *ecclesiastical* as well as a *civil* year. The first began in the month of Nisan or Abib, which answers to part of our March and April, because about this time the Israelites came out of Egypt. By this they reckoned their feasts The second began in the month Tisri, about the middle of our September, because they fancied the world to have been created about that time. The ancient Roman year was lunar, and the first month was March; then followed April, May, June, Quintilis, Sextilis, September, October, November, December, so that the *numeral* months were named according to their order in the series. Much confusion crept into the computation of the year, through inattention or ignorance, till the time of Julius Cæsar The year, as reformed by him, is a solar year, consisting of 365 days, except every fourth year, called bissextile, which contains 366. The *Julian* year, therefore, is 364 days 6 hours, exceeding the *Solar* year by 11 minutes, which in 131 years amount to a whole day Thus stood the year till the reformation of the Calendar by Pope Gregory. The *Gregorian* year is, consequently, the Julian year corrected, and is the year now used in Europe. From the difference between this and the Julian year arises the distinction of Old and New style ——The Mahometans begin their year when the sun enters Aries; the Persians in the month answering to our June, the Chinese and most of the Indians begin it with the first moon in March. At Rome there are two ways of computing the year—the one beginning at the Nativity, which the notaries use; the other in March, on occasion of the incarnation, and it is from this the papal bulls are dated. The civil or legal year in England, as well as the historical year, commences on the 1st of January. The church, as to her solemn service, begins the year on the first Sunday in Advent, which is always the nearest Sunday to St. Andrew's Day, whether before or after. See CALENDAR, CHRONOLOGY, CYCLE, &c] ——*Year and day*, in law, signifies a certain time that by law, in many cases, determines a right, or works prescription; as in the case of an estray, if the owner should not challenge it within that time, it becomes forfeited to the lord; so of a wreck, &c.

YEAST (*gest: Sax.*), the barm or froth which rises during the vinous fermentation of vegetable juices. It is a flocculent viscid matter, insoluble in water and alcohol; from its appearance under the microscope, it is now believed to consist of a fungoid growth. It putrifies in a warm atmosphere, and excites fermentation in saccharine and mucilaginous liquids It is also used in the making of bread, its property being to raise the dough, and by that means render it light and more wholesome.

YEL'LOW (*gealewe: Sax*), in Chromatics, one of the seven, or rather three, primary colours. It contains the smallest amount of chemical rays, and is therefore used by photographers, when light, destitute of chemical action, is required; thus, when a sensitive plate is to be examined

YEL'LOW-BIRD, in Ornithology, the *Fringilla tristis*, or American goldfinch, an active and gregarious bird, of a rich lemon-yellow colour; the crown, wings, and tail black The female and young are of a brown olive colour; and in winter the male assumes the same sober livery When caged, its song greatly resembles that of the canary

YEL'LOW-FEVER, in Medicine, a malignant disease frequent in hot climates, which often suffuses the skin with a yellowish colour. It is a bilious remittent fever.

YEL'LOW-HAMMER, or AMMER, the *Emberiza Citrinella* of ornithologists, a Passerine bird about 7 inches in length, found generally throughout Europe Its throat and the crown of the head are yellow. It is also called the yellow bunting

YEL'LOWS, a disease of horses, cattle, and sheep; in which the eyes are tinged with a yellow colour, proceeding often from obstructions in the gall-ducts.

YEN'ITE, in Mineralogy, a ferruginous silicate of lime, from Elba. It occurs both crystallized and massive, the form of the crystals being that of a rhomboidal prism. It somewhat resembles hornblende. This mineral is called *yenite* or *jenite*, in commemoration of the battle of Jena.

YEO'MAN (*geoman: Sax*), in English polity, a *commoner*, or a plebeian of the first or most respectable class. The term is now usually applied to a man who cultivates his own land for his support. In ancient times it denoted one of those who held *folk land*; that is, had no *fief*, or bookland, and therefore did not rank among the *gentry*. What the yeoman possessed, however, he possessed independently; he was, therefore, no man's vassal. To understand the true condition of the ancient yeoman, it must be observed that there were some lands which never became subject to the feudal system. These were called folk-lands, or the lands of the people. When, therefore, it is said that the sovereign is the lord of the soil of all England, the assertion is not strictly true. He is certainly the lord paramount of all fiefs; but he has no such reversionary interest in lands that were never held in fee. [See FEUDAL SYSTEM, GAVEL-KIND, &c]——The collective body of yeomen or freeholders is termed *Yeomanry*.——*Yeomanry of the Guard*. [See GUARD.]

YEO'MANRY CAV'ALRY, a body of volunteers composed chiefly of small landowners and farmers, meeting once a year in several of the English counties for military exercise. They receive a grant from government, and are under the command of the lord-lieutenant, who appoints the officers.

YEW (*iev: Sax.*), the *Taxus baccata* of botanists, an evergreen tree allied to the conifers, but having a fleshy fruit, not a dry cone. It is common in England and in many parts of the North of Europe. The wood, which is peculiarly hard, smooth, and tough, was manufactured into bows; but since the introduction of firearms, the tree is no longer planted except for ornament. The wood is beautifully veined, and susceptible of a very high polish. The leaves are extremely poisonous, and cattle are frequently destroyed by them.

YT'TRIA, in Mineralogy, the oxide of *yttrium*, a very rare earth, obtained from a species of *gadolinite*, discovered at Ytterby, in Sweden; hence its name. It resembles glucina in several of its properties. It is smooth and insipid, is infusible alone, but vitrifies with borate of soda. It combines with the acids, and is precipitated from those solutions by ammonia and prussiate of potash. It is perfectly white; has neither taste nor smell.

YT'TRIUM, a brittle metal of a dark-grey colour.

YT'TRO CERITE, a massive mineral, of a greyish or violet-blue colour. It consists of fluoric acid, yttria, oxide of cerium, and lime.

YT'TRO-TAN'TALITE, in Mineralogy, an ore of tantalum, containing yttria and oxide of columbium. It occurs massive, has a metallic lustre, and is of a blackish-brown colour. Under the blowpipe it decrepitates at first, but melts, by increase of heat, into a greenish-yellow clay.

YULE (*gehul: Sax.*), the name anciently given to Christmas. The word is probably Celtic: *wyl*, or *gywl*, in Welsh, signifies a holiday; perhaps the French word *noel* is derived from the same source.

YUNX, in Ornithology, the *Wryneck*, or *Yunx torquilla*, a bird which is nearly allied to the woodpecker. It makes no nest, but lays eight or ten eggs on the bare wood in hollow trees. In England it is a bird of passage, generally appearing a few days before the cuckoo. Its food consists of ants. It is never seen in flocks, and in pairs only during the spring and summer. Its name of *wryneck* is derived from a habit of twisting its neck in a singular manner.

Z

Z, the last letter of all modern languages, is generally considered as a double consonant, having in some languages the sound of *ts*, or *ds*. It begins no word originally English; and, though found in Saxon alphabets, it is not in any word originally Teutonic. As a numeral, Z stands for 2,000, and with a dash over it, for 2,000,000.

ZAC'CHO, in Architecture, the lowest part of the pedestal of a column.

ZAF'FRE (*zaffir: Germ.*), an impure oxide of cobalt, employed for giving a blue colour to pottery-ware and porcelain. The blue of zaffre is the most solid and fixed of all the colours employed in vitrification. It suffers no change from the most violent fire. It is successfully employed to communicate shades of blue to enamels, and to the crystal glasses made in imitation of some opaque and transparent precious stones, as the Lapis-lazuli, the Turquoise, the Sapphire, and others of this kind. The zaffre of commerce is never quite pure.

ZE'BRA, the *Asinus Zebra* of Zoologists, an animal of the horse family, is beautifully marked with stripes; and has a short mane, erect ears, and tail like an ass. It is a native of South Africa, about the size of a mule, and is wild, swift, and vicious. The *Asinus Burchellii*, another striped species, but more closely related to the horse than the last, is also a native of South Africa.

ZECHARI'AH, one of the minor prophets, who lived in the reign of Darius Hystaspes. The design of the first part of Zechariah's prophecy, like that of his contemporary Haggai, is to encourage the Jews to proceed with rebuilding the Temple. His style, like that of Haggai, is for the most part prosaic, especially towards the beginning; the last six chapters are more elevated; for which reason, among others, these six chapters are, by many commentators, ascribed to the prophet Jeremiah.

ZED'OARY, an aromatic stimulating root, employed in medicine. It is the produce of some plants belonging to the genus *Curcuma*, allied to those which produce ginger, cardamoms, and East Indian arrowroot.

ZEINE (*zea*, a kind of grain: *Gr.*), a substance of a yellowish colour, soft, insipid, and elastic, procured from the seeds of Indian-corn. It resembles gluten, but contains no nitrogen.

ZEM'INDAR (*zemin*, land: *Pers.*), in India, a feudatory or landholder who governs a district of country, and is receiver of the taxes. His jurisdiction is called a *zemindary*. It is liable to be sold by the government for arrears of revenue; in which case the leases of the ryots would be set aside. At present the land-tax is collected in India in three ways: by the *Zemindar settlement*, in which the Zemindar is responsible for it; by the *Mouzawan* or *Village settlement*, in which the collectors contract with the head-man of the village; and the *Ryotwari* or *Cultivator's settlement* in which the peasantry pay direct themselves.

ZEND-AVESTA (the living word: *Pers.*), the sacred books of the Parsees in India, and Guebers in Persia: books ascribed to Zoroaster, and supposed to contain his revelations. The language, after having been deciphered with difficulty, has been found to have a close relationship with Sanscrit.

ZEN'ITH (*Arab.*), in Astronomy, that point in the visible celestial hemisphere which is vertical to the spectator, and from which a direct perpendicular line passing through the spectator, and extended, would proceed to the centre of the earth. Each point of the surface of the earth has therefore its corresponding zenith——The *zenith distance* of a heavenly body is the arc intercepted between the body and the zenith, being the same as the co-altitude of the body.

ZE'OLITE (*zeo*, I boil; and *lithos*, a stone: *Gr.*). Many mineral substances have been confounded under this name, particularly such as, when fused under the blowpipe, melt with considerable ebullition. They generally consist of silica, alumina, lime, and water.

ZEPHANI'AH, a canonical book of the Old Testament, containing the predictions of Zephaniah, the son of Cushi, and grandson of Gedaliah; being the ninth of the twelve lesser prophets. He prophesied in the time of king Josiah, a little after the captivity of the ten tribes, and before that of Judah, so that he was contemporary with Jeremiah.

ZEPH'YRUS, or **ZEPH'YR** (*zephuros; from zophos*, darkness—which commences when the sun reaches the west: *Gr.*), the west wind; a wind blowing from that cardinal point opposite to the east. The poets personify it, and represent Zephyrus as a youth, and as the gentlest of all the deities of the woods. It is also called Favonius; though some consider Zephyrus and Favonius to be different.

ZER'DA, in Zoology, the *Megalotis* or Fennec, a beautiful little animal closely allied to the dog, and found chiefly in North Africa. It is of a yellowish-white colour, about ten inches in length, with a pointed nose, long whiskers, large black vivid eyes, and is remarkably fleet.

ZE'RO (*Ital.*), the point of a thermometer from which it is graduated. The zero of Fahrenheit's thermometer is fixed at the point at which the mercury stands when immersed in a mixture of snow and common salt, 32° below the freezing point. In Wedgwood's pyrometer, the zero corresponds with 1077·5° on Fahrenheit's scale. The zero of Reaumur's and of the Centigrade thermometers is the point at which water congeals.

ZE'TA, a closet or small chamber, with pipes running along the walls, to convey into it fresh air, or warm vapour from below.——Also, the Greek letter Z.

ZETET'IC (*zēteo*, I seek: *Gr.*), in Mathematics, an epithet applied to that method of investigation which proceeds by inquiry, or the solution of problems.

ZEUG'MA (*Gr.; from zeugnumi*, I join), a figure in Grammar, in which two subjects *are used jointly* with the same predicate; which strictly belongs to only one.

ZIBET', in Zoology, the *Viverra zibetha*, a carnivorous mammal, striped with wavy black lines and having an annulated tail. The *Viverra zibetha* holds the same place on the Asiatic continent that the *Viverra civetta* holds in Africa, and the *Viverra rasse* in Java.

ZIBE'THUM, *civet*, the soft, unctuous, odoriferous substance, produced by the *Viverra vivetta*, and *Viverra zibetha* or civet-cat. It has a grateful smell when diluted, an unctuous subacrid taste, and possesses stimulating, nervine, and antispasmodic virtues.

ZINC (*Germ.; from zinke*, a spike—from the forms it often assumes after fusion), a metal termed in commerce *spelter*. Its ore was known long before a mode of reducing it was discovered. It is procured either from *calamine*, the native carbonate, or from *blende*, the native sulphuret. It is of a blueish-white colour; its texture is lamellar and crystalline, and its spec. grav. about 7. It is tough and untractable under the hammer at common temperatures; it becomes brittle at 500°, and fuses at 770°; but between 220° and 320° it becomes malleable and ductile, so that between these temperatures it may be rolled into sheets, or drawn into wire. The zinc thus annealed and wrought retains the malleability it had acquired. When broken by bending, its texture appears as if composed of cubical grains. It may be granulated, like the malleable metals, by pouring it, when fused, into cold water, or if it be heated nearly to melting, it is then sufficiently brittle to be pulverized. Soon after it becomes red-hot, it burns with a dazzling white flame, of a bluish or yellowish tinge, and is oxydized with such rapidity that it flies up in the form of a white flocculent mass, called the flowers of zinc, philosophical wool, or *nihil album* (white nothing). This is generated so plentifully that the access of air is soon intercepted; and the combustion ceases, unless the matter be stirred, and a considerable heat kept up. The white oxide of zinc is not volatile, but is driven up merely by the force of the combustion; when it is again urged by a strong heat, it becomes converted into a clear yellow glass. If zinc be heated in close vessels, it rises without decomposition. The greater part of the zinc-works are situated in the neighbourhood of Birmingham and Bristol. The manufacture of brass, which has been long one of the staple articles of these towns, was probably the cause of the introduction of this branch of industry, at the period when brass began to be made by the direct union of copper with metallic zinc instead of calamine. Iron is often coated with zinc to preserve it from the action of the atmosphere, and is then termed 'galvanized.'

ZIN'GIBER (*zingibberis: Gr.*), in Botany, a genus of herbaceous plants containing the gingers. The white and black ginger are both the produce of the same plant, the difference depending on the mode of pre paring them. Ginger is considered as an aromatic, antispasmodic, and carminative; it is serviceable in flatulent diseases, debility, and in torpid and phlegmatic constitutions to excite brisker vascular action.

ZIR'CON, a mineral originally found in Ceylon, in the sands of rivers, along with spinel, sapphire, tourmalin, and ironsand. Zircon, hyacinth, and zirconite are regarded as varieties of the same species. They are essentially composed of the earth zirconia, with silica, and a minute portion of iron. Its common form is a rectangular four-sided prism.

ZIRCO'NIA, a rare earth extracted from the zircon; it is an oxide of zirconium. The salts of zirconia, unlike those of alumina and glucina, are precipitated by all the pure alkalis, and are insoluble when they are added in excess.

ZIR'CONITE, in Mineralogy, a variety of the *zircon*.

ZIRCO'NIUM, the metallic base of zirconia; it does not resemble a metal, being like charcoal powder. Heated in the air, it burns with almost explosive violence, forming the oxide.

ZO'DIAC (*zōdiakos kuklos*, the *Zodiac circle*: from *zōon*, an animal; on account of the constellations: *Gr.*). The word *circle* is omitted. In Astronomy, an imaginary ring or broad circle, in the heavens, in form of a belt or girdle, within which the greater planets all make their revolutions. In the very middle of it runs the ecliptic; and its breadth, comprehending the deviation or latitudes of the earlier known planets, is by some authors considered to be 16, by some 18, and others 24 degrees. The zodiac, cutting the equator obliquely, makes with it the same angle as the ecliptic, which is its middle line; which angle, continually varying, is now nearly equal to 23° 27′ 36·52″. This is called the obliquity of the ecliptic, and constantly varies between certain limits, which it can never exceed. The zodiac is divided into 12 equal parts, of 30 degrees each, called the signs of the zodiac, being so named from the constellations which anciently agreed with them [see CONSTELLATION]. But the stars having a motion from west to east, those constellations do not now correspond to their proper signs [see PRECESSION OF THE EQUINOXES]. And, therefore, when a star is said to be in such a sign of the zodiac, it is not to be understood of that constellation, but only of that division or 12th part of it.—It is a curious fact, that the solar division of the Indian zodiac is the same in substance as that of the Greeks; and yet that it has not been borrowed either from the Greeks or the Arabians. The identity or, at least, striking similarity, of the division has led to a supposition that the Brahmins received it from the Arabs. But it has been known among the Hindoos from time immemorial. The signs of the zodiac are Aries, Taurus, Gemini, Cancer, Leo, Virgo, Liber, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces. They are counted from the vernal equinox, which is now in the constellation Pisces. Representations of the zodiac have been found in several ancient Egyptian temples, and have given rise to much discussion.

ZODI'ACAL LIGHT (*zōdiakos*, belonging to the zodiac: *Gr.*), in Astronomy, a nebulous aurora which accompanies the sun. It was supposed by Kepler to be the solar atmosphere, but it was accurately described by Cassimi, who gave it its present name. It appears immediately before sunrise in the months of September, October, and November, or after sunset in the months of March, April, and May. It has a conical or lenticular form, and is most distinct in tropical countries. Various hypotheses have been invented regarding it, that being considered the most probable which supposes it to be the ether, that is believed to fill space, loaded with the materials of the tails of numerous comets.

ZOLL'VEREIN (*Zoll*, toll; *Verein*, union: *Ger.*), a union of German States, headed by Prussia, formed for the purpose of establishing common regulations as to the customs duties.

ZONE (*zōnē*, a belt: *Gr.*), in Geography, a circular division of the earth with reference to the temperature. There are five zones: the *torrid*, extending from tropic to tropic, and twice the sun's greatest declination, or 47°, in breadth; the two *temperate* zones, situated between the tropics and polar circles, each 43 in breadth; and the two *frigid* zones, situated between the polar circles and the poles. The zones are distinguished from one another by various phenomena. To the inhabitants of the torrid zone the sun is vertical twice a year. In the middle of that zone the days and nights are always equal, each being 12 hours, and the twilight is short because the sun descends perpendicularly below the horizon. Within its limits there are only two seasons in the year, viz., winter and summer.

ZO'OLITE (*zōon*, an animal; and *lithos*, a stone: *Gr.*), an animal substance purified.

ZOOL'OGY (*zōon*, an animal; *logos*, a discourse: *Gr.*), the science which is concerned with the structure and classification of the beings constituting the ANIMAL KINGDOM. The chief divisions of this subject are treated of in this volume under the heads of VERTEBRATA, MAMMALIA, ORNITHOLOGY, AMPHIBIA, REPTILES, ICHTHYOLOGY, MOLLUSCA, ARTICULATA, ENTOMOLOGY, INSECTS, MYRIAPODA, CRUSTACEANS, CIRRHIPEDES, ANNELIDA, ROTATORIA, ENTOZOA, ECHINODERMATA, ACALEPHÆ, ZOOPHYTES, PROTOZOA, SPONGES.

ZOON'OMY (*zōon*, an animal; and *nomos*, a law: *Gr.*), the laws of animal life, or that science which treats of the phenomena of animal life, their causes, consequences, and relations.

ZOO'PHYTES (*zōon*, animal; *phuton*, plant: *Gr.*), an extensive class of invertebrate animals usually called *Polypes*, in the sub-kingdom *Radiata*. The appearance of these animals is very various; some secrete a horny tube in which they live; others secrete a great number of calcareous spicula [see ALCYONIUM, GORGONIA]; others secrete a hard stony substance known as CORAL; others a flexible branching body resembling a small bush [see ANTIPATHES];

whilst many species only secrete mucus [SEA-ANEMONE]. The simplest form of the animal is that of a fleshy bag with an opening at one end, forming the mouth, round which is placed a series of tentacles. The other end is the part by which it adheres to another object. The HYDRA, which is common in pools, where it adheres to plants, is of this simple structure. Most polypes are able to benumb other animals with which they may be brought into contact, and they have in their tissues offensive weapons possessing a stinging power which they discharge when irritated. They are all destitute of special organs of sense, nor has any distinction of sex been discovered amongst them. Most, if not all, deposit ova; many are also propagated by division or budding [see GEMMATION]. Some species consist of simple individuals; others are compound animals, such as the Corals and Gorgonias.

ZOOT'OMY (*zoon*, an animal; and *temno*, I cut up: *Gr.*), that branch of anatomical science which relates to the structure of the lower animals. [See COMPARATIVE ANATOMY.]

ZORILLA, in Zoology, a carnivorous quadruped closely allied to the weasels, having the back and sides marked with stripes of black and white, the last tinged with yellow; the tail long and bushy, partly white, and partly black; the legs and belly black. This animal inhabits South Africa.

ZU'MIC ACID (*zumē*, leaven; from *zeo*, I bubble up: *Gr.*), in Chemistry, an acid formed in sour bread, and vegetable substances which have undergone acetous fermentation.

ZUMOL'OGY (*zumoo*, I make to ferment; and *logos*, a discourse: *Gr.*), a treatise on the fermentation of liquors, or the doctrine of fermentation.

ZUMOM'ETER, or ZUMOSIM'ETER (*zumē*, ferment, or *zumōsis*, fermentation; and *metron*, a measure: *Gr.*), an instrument for ascertaining the degree of fermentation occasioned by the mixture of different liquids, and the degree of heat which they acquire in fermentation.

ZUR'LITE, a mineral, found in Mount Vesuvius, with calcareous spar. It occurs in rectangular prisms, or in botryoidal masses, of an asparagus-green, inclining to a grey colour. It is opaque, yields to the knife, and melts with borax into a black glass.

ZYGODAC'TYLOUS (*zugon*, a pair; and *daktulos*, a finger: *Gr.*), an epithet for an order of birds which have the feet furnished with two toes before and two behind, as the parrot.

ZYGO'MA (*Gr.*; from *zugoo*, I yoke together—because it transmits the tendon of the temporal muscle, like a yoke), in Anatomy, a bone of the head, or rather two processes of bones; the one from the *os temporis*, the other from the *os male;* these processes are hence termed the *zygomatic processes*, and the suture that joins them together is denominated the *zygomatic suture.*

ZYMO'TIC (*zumotikos*, causing to ferment: *Gr.*), in Medicine, diseases caused apparently by the reception into the system of a virus, or poison, which is diffused through the frame, and operates upon it like a ferment or leaven. In the Registrar-general's report, the following diseases are grouped together as *zymotic:*—Smallpox, measles, scarlatina, hooping-cough, croup, thrush, diarrhœa, dysentery, cholera, influenza, scurvy, ague, remittent fever infantine fever, erysipelas, and a few others.

SUPPLEMENT

TO THE

SCIENTIFIC AND LITERARY TREASURY.

The reader is requested to observe that the words printed in small capitals in the body of an article are intended as cross references, and that when the articles referred to are in this Supplement they are distinguished by the addition (*St.*).

ABD, a common prefix to Turkish and Arabic names, meaning servant; *e.g.*, Abdallah, the servant of God.

ABENCERRAGES, a noble Moorish family of Granada, descendants of Ebn Serraj, who opposed the king Abu Hassan. The whole family was enticed into the Alhambra and slaughtered by the king's orders about 1460. This formed the subject of a well-known story by Chateaubriand.

ABIOGENESIS (*a*, without; *bios*, life; *genesis*, generation: *Gr.*), the theory that living forms may be directly produced from non-organised bodies, such as carbonic acid, ammonia, and water. It is sometimes termed heterogenesis (*heteros*, unlike: *Gr.*), or spontaneous generation. The opposite and generally accepted theory, *biogenesis*, asserts that all organised bodies proceed from pre-existing forms of a similar kind.

ACADEMY, FRENCH. [See INSTITUTE, FRENCH (*St.*).]

ADVENTITIOUS BUDS, in Botany, are those which do not make their appearance in the axils of leaves, or at the growing apex of a plant. Under ordinary conditions they are of rare occurrence, and they are considered abnormal; but ferns grown under glass often produce them abundantly.——ADVENTITIOUS ROOTS are those produced above the ground, and they are therefore often termed aërial. The ivy clings to its support by such roots.

ADVERSARIA (*Lat.*), a book of notes.

AGGLUTINATIVE (*ad*, to; *glutinare*, to glue or solder: *Lat.*), a term applied by philologists to such languages as those of the ALTAIC (*St.*) or Turanian division, which do not inflect their verbs, but add other words to them when time and other varieties of signification are intended to be expressed. But Mr. E. B. Taylor says that the distinction between the so-called inflecting languages, such as Greek and Hebrew, and the agglutinating languages is much exaggerated, for he thinks that inflection is a kind of extreme agglutination.

AGNOSTICISM (*agnostos*, unknown: *Gr.*), the doctrine which teaches that nothing is known as to the manner in which the world came into existence.

AGORA (*agora*: *Gr.*), in ancient Greece a general assembly for dealing with public affairs; also, a place where such assemblies usually met; a forum, a market-place.

AHRIMANES. [See ORMUZD (*St.*).]

ALIZARINE (from the Arabic name for madder), a red colouring matter used in dyeing and obtained from the root of the madder plant. An efficient substitute for it is obtained from coal tar, and is called artificial alizarine. This is rapidly displacing the madder dye.

ALTAIC or **UGRO-ALTAIC** Languages, a group termed Turanian and Scythian by some writers. In addition to Turkish and Mongolian, they comprise the Finno Ugric tongues, viz., the Finn, Esthonian, Lapp, &c., spoken on the borders of the Baltic; the Permic tongues of the Ural Mountains; the Bulgaric tongues of the Volga; and the Ugric tongues of the Danube and Obi, *e.g.*, the Magyar of Hungary.

ALTAZIMUTH INSTRUMENT, in Astronomy, a telescope mounted in such a way as to be capable of motion in two planes at right angles to each other, the amount of its angular motion in each being measured on two circles co-ordinate to each other, whose planes are parallel to those on which the telescope moves. The principal axis of the mounting occupies a vertical position, and whilst one circle corresponds to the celestial horizon, the other corresponds to a vertical circle of the heavens. The angles measured on the former circle are differences of azimuth, those on the latter are zenith distances or altitudes.

AMESS or AMICE (*amictus: Lat.*), a square piece of linen worn on the shoulders by priests in the Roman Catholic Church. Amongst the ancient Romans the amictus was a garment worn over the tunic.

AMŒBA, a minute animal found in stagnant water, and belonging, like the FORAMINIFERA, to the class of Rhizopoda, but it is destitute of a shell. It is a mere shapeless speck of sarcode without skin or organs of any kind, but possesses both a nucleus and a pulsating cavity. It moves slowly by protruding a portion of its mass, and then following with the rest. Its food is drawn into its body at any part, and what remains indigested is rejected in the same manner. The individual increases by dividing and forming two. A still more rudimentary form of animal life is the homogeneous particle of protoplasm destitute of nucleus and pulsating cavity, which Professor Haeckel named *Protamœba*. It is found in the fresh waters of Germany.

AMPHIOXUS (*amphi*, at each end; *oxus*, sharp: *Gr.*), the Lancelet, a ribbon-shaped animal about two inches long, living in sand at the depth of a few fathoms off the British coast. It possesses a spinal cord enclosed in a gelatinous sheath, but without vertebræ, cranium, or bones. It is, however, placed in the order of fishes, of which it is the lowest member. Insignificant as it appears to be, it is a very important link in tracing the descent of animal existences, and some anatomists look upon it as the only living animal which can give us an approximate conception of man's earliest vertebrate ancestors.

AMPHITRYON, a mythic Greek hero, whose name is often used by the French for a host, in allusion to the story that during Amphitryon's absence from home, Jupiter in his likeness paid a visit to his house and gave a feast. Before its conclusion the real Amphitryon returned, and claimed the honours of the position; but the guests rejected his claim, declaring that the true host was he who gave the feast; or as Molière expressed it, 'Le véritable Amphitryon est l'Amphitryon où l'on dine.'

AMPLITUDE, the, of a vibration or oscillation, means the extent of the swing of the body from its extreme point on one side, to the extreme point on the other. In sonorous vibrations the loudness of the sound is in proportion to the square of the amplitude. It has been calculated that the amplitude of a vibration sufficient to produce sound is less than the ten millionth of a millimetre.

ANACRUSIS (*ana krousis*, a keeping back: *Gr.*), in Prosody and Music, the ictus or beat by which the time of a verse or melody was measured.

ANDIRONS, the iron supports in old fireplaces of the ends of the logs of wood which were burned on the hearth. Some suppose the word to be a corruption of *end irons*. Their extremities facing the room were often fancifully ornamented, and they were sometimes called dogs, the ornament having often been a dog's head.

ANIMISM (*anima*, a soul: *Lat.*), the belief in spiritual existences. Many different ideas relating to the external world are comprehended under this term.

APOLOGY (*apologia*, vindication: *Gr.*), in Literature, a treatise composed in support or defence of some doctrine, book, or person. Hence *apologetic* writings, as Bishop Watson's 'Apology for the Bible.'

APOSIOPESIS (*Gr.*), in Rhetoric, the breaking off by design in the middle of a sentence, and commencing another one.

ARAGONITE, one of the natural forms of carbonate of lime, originally found in Aragon, but afterwards in many other places. Its crystals are hexagonal prisms. It is deposited by some hot springs, and it forms the troublesome deposit of steam boilers.

ARAMAIC, a Semitic language which had two principal dialects, the Syriac and Chaldean. It derived its name from Aramaa, signifying 'highland,' that part of Syria which is on the left bank of the Jordan.

ARAUCARIA (*Araucans*, the Indians of Chili), a genus of handsome coniferous trees, of which only one is cultivated in the open air in England, the *A. imbricata*, a native of Chili, the other species being too tender for our climate. The Norfolk Island pine, young plants of which are frequently seen in hot-houses, is *A. excelsa*. In New Caledonia and some neighbouring islets grows the *A. Cookei*, a tree of so singular a habit, that when first seen from the deck of his vessel, Captain Cook says, that his 'philosophers were positive they were pillars of basaltes, like those which compose the Giant's Causeway.'

ARBOR SATURNI (the tree of Saturn: *Lat.*), the tree-like deposition of metallic lead from a salt in the presence of metallic zinc. [See ARBOR DIANÆ.] The alchemists gave the name of Saturn to lead.

ARC, ELECTRIC, the light which appears between the carbon or other electrodes, when a sufficiently powerful current is passing.

ARCHIMANDRITE (*archimandrites: Gr.*), the chief of a monastery in the Greek or Eastern Church.

AREOMETER (*araios*, thin; *metron*, a measure: *Gr.*), an instrument for measuring the densities of fluids. Hydrometers and saccharometers are areometers.

ARGAN TREE, a tree belonging to the genus *Argania*, nat. order *Sapotaceæ*, which grows in Morocco. Camels and other domesticated animals are fed on its fruit, a drupe, and from the kernel of the nut an oil is extracted, which is largely used in the country.

ARMATURE, a piece of iron placed at the poles of a horseshoe magnet, which has the effect of preserving the magnetic power for a long time.

ARNAOUTS, the Turkish name of the Albanians, who call themselves Skipetar. They are believed to be descendants of the ancient Thraco-Illyrians. In religion they are Mohammedans.

ASSEGAI, a spear of wood tipped with iron, used by the Caffres of South Africa.

ASTATIC (*astatos*, not constant: *Gr.*). In the science of Magnetism a needle which is not affected by the earth's magnetism, and which, when freely suspended, will steadily remain in any position in which it may in a horizontal plane be placed, is styled astatic. Such a needle may be constructed by combining two magnetised needles, so that their poles are turned in opposite directions.

ASTEROIDS. The discovery of new ones has proceeded rapidly of late years. Up to the end of 1879, the number of known asteroids was 211. [See ASTEROIDS.] One, which has received the name of Hilda, is remarkable for the length of its period of revolution round the sun, nearly eight years.

ATMOSPHERE. At the level of the sea the mean pressure of the atmosphere is about 15 lbs. on the square inch. When gases, &c., are subjected to compression by mechanical means, the pressure is often stated in terms of the atmospheric pressure as a unit. Thus a pressure of ten atmospheres means a pressure of 150 lbs. to the square inch.

ATTWOOD'S MACHINE, an apparatus invented by Mr. Attwood of Cambridge at the close of the last century, for the purpose of illustrating and verifying the laws of falling bodies.

AURANTIACEÆ, in Botany, an order of polypetalous trees and shrubs, natives of warm climates, and having leaves abounding with a fragrant volatile oil. To this order belongs the genus CITRUS (*St.*), containing the CITRON, LEMON, ORANGE, and SHADDOCK. The Wampee, a Chinese fruit, is produced by the *Cookia punctata;* the Bengal Quince or Marmelos, a delicious East Indian fruit, is yielded by the *Ægle marmelos;* the Elephant Apple is the fruit of *Feronia elephantum*, which grows on the Coromandel coast; and there are other fruit trees in the order.

AUROCHS, more properly AUERROCHS (*Germ.*), the extinct *Bos primigenius*, which was living in England and Germany in Cæsar's time. It is supposed to be the progenitor of the half-wild cattle in Chillingham Park. Its bones are sometimes disinterred in bogs and caves.

AUTOCHTHONES (*autos*, itself; *chthon*, the soil: *Gr.*), the aboriginal inhabitants of a country, which the Greeks expressed by saying they had sprung out of the ground.

AUTONOMY (*autos*, itself; *nomos*, a law: *Gr.*), in Politics, the possession by a country of the right to make its own laws.

AVENTURINE, in Mineralogy, rock crystal with disseminated scales of mica, or crystals of copper, found in several parts of the world. Artificial aventurine is glass in which minute particles of brass or copper are mixed. It is said to derive its name from its having been first made at Venice by the accidental (*a ventura*) fall of some brass filings into melted glass. The mineral was named from its resemblance to the artificial substance.

AZOIC (*a*, without; *zoe*, life: *Gr.*), a term applied to geological strata in which no organic remains have been found.

AZTECS, the principal race of people living in Mexico when the Spaniards discovered the country in the thirteenth century. They are thought to have come from Nicaragua, where it is said there is still a tribe speaking their language. They were powerful and civilised, but their religious rites were very sanguinary.

B

BACTERIA (*bacterion*, a little rod: *Gr.*), minute rod-shaped vegetable organisms which are found abundantly in animal or vegetable infusions after they have been exposed to the air for some hours. The germs are believed to float about in the atmosphere until they find a suitable place for their development, when they multiply with great rapidity. It has been thought that various diseases of the human body arise from bacteria having effected an entrance into it.

This is the so-called germ theory of disease.

BAILY'S BEADS, in Astronomy, the red prominences seen at the edge of the sun at the time of a total eclipse. They are outbursts of ignited hydrogen, and were so named from Mr. Baily the astronomer.

BALAUSTA (*balaustion*, the flower and young fruit of the pomegranate: *Gr.*), the name given by botanists to the apple-like fruit of the pomegranate (*Punica granatum*, nat. order *Myrtaceæ*), which they consider a modification of the berry. Its structure is very peculiar, and perhaps unique in the vegetable kingdom, as the fruit is many-celled and there are two rows of carpels, one placed above the other.

BANTU (*abantu*, people: *Caffre*), the name given by philologists to the languages spoken in Africa from the Cape Colony northwards as far on the west to the 8th parallel of N. latitude and on the east up to the equator. It includes numerous forms which are usually divided into three groups: (1.) The eastern languages, Caffre, Zulu, and those spoken on the Zambesi and in the neighbourhood of Zanzibar, (2.) the middle group, spoken by the Basutos, Bechuanas, &c., (3.) the western group, spoken by the races on the lower course of the Congo, and in the country claimed by the Portuguese on the west coast.

BANYAN TREE, the *Ficus Indica* of botanists, is remarkable for having large horizontal branches that send down roots which enter the ground, become stout, and serve as props. In this way a single tree will form a grove. A similar mode of growth is possessed by the *Ficus columnaris* of Howe's Island, and is occasionally seen in the Moreton Bay Fig (*F. macrophylla*) and the common New South Wales Fig (*F. Australis*).

BAPTISTERY, the place in churches where the baptismal font is placed and the rite of baptism performed. In some Italian cities it is a large detached building, circular or octagonal in plan, covered by a dome. Those of Florence and Pisa are celebrated for their architecture and connection with early art.

BARITONE (more properly BARYTONE; *barus*, deep, *tonos*, tone: *Gr.*), the low tenor or high bass voice of males.

BARKER'S MILL. [See TURBINE.]

BARNABITES, an ecclesiastical order founded at Milan in 1430. The members devote themselves to nursing the sick, cure of souls, education, &c., without seeking higher preferment. There are about twenty colleges in Italy and Austria, their headquarters being at Rome.

BAROSCOPE (*baros*, weight, *scopein*, to see: *Gr.*), the name of an apparatus for showing that the weight of a body in the air is affected by the upward pressure of the air upon the body. It consists of a balance, to the opposite arms of which are attached two balls of very unequal sizes which balance each other in the air. When this apparatus is placed under the receiver of an air-pump, the larger ball will be seen to descend as the air is exhausted, thus showing that the upward pressure of the air had previously prevented it overbalancing the smaller ball.

BASHI-BAZOUKS (those who fight without science: *Turk.*), the irregular soldiers of the Turkish army, comprising men of all races. They have earned an unenviable notoriety for rapine and cruelty.

BESSEMER STEEL, steel made by the process invented by Sir H. Bessemer, of driving air into melted iron so as to get rid of part of the carbon.

BIGNONIACEÆ, in Botany, a natural order belonging to the class of Calicifloræ, and containing trees and shrubs which are often climbers. The genera *Bignonia* and *Tecoma*, inhabitants of warm countries, have many species with handsome trumpet shaped flowers. *Catalpa syringifolia* with purple flowers, has been introduced as an ornamental tree into Europe. The *Crescentiaceæ*, to which the CALABASH TREE belongs, are sometimes considered a section of this order.

BILLET MOULDING, an ornament employed in Mediæval Architecture, around doors and windows. It is shaped like a number of wooden billets piled one above another, and is frequently accompanied with the zigzag moulding.

BILLION (*Fr.*), a million of millions (1,000,000,000,000). In French, billion or milliard signifies a thousand millions.

BINOMIAL THEOREM, in Mathematics, a method of expanding $(a + b)^n$ into a series, either finite or infinite, as the case may be, of powers of a and b. In other words, it is a formula for expressing any power of a binomial quantity. It is a theorem of special importance in elementary algebra, and was discovered by Sir Isaac Newton.

BUTYL, in Chemistry, a hydrocarbon radical analogous to methyl, ethyl, &c., and forming like them alcohols, ethers, &c. Butylic alcohol is lighter than water. If applied to the lips and tongue when in a pure state, it produces a sensation of burning, and after the burning sensation has passed off there remains an extreme feeling of numbness in the part. It has been found useful in relieving pain such as toothache, by applying it to the part affected. Diluted with water, it is not unpleasant to take when sweetened.

BY PRODUCT, anything produced in the course of manufacturing the article which is the main object of the process; for example, tar, in distilling coal for gas.

C

CACHET, Lettres de (*cachet*, seal: *Fr.*), private sealed letters or papers which the kings of France before the Revolution were in the habit of issuing for the arrest of persons without any cause being alleged, and such persons were either imprisoned or expelled the kingdom without trial. They were abolished by a decree of the National Assembly in 1789.

CAFTAN (*Turkish*), a robe-like article of dress worn by men.

CAIRNGORM STONE, a variety of smoky quartz found in Scotland, and named from the mountain Cairngorm in Inverness-shire. It is cut and polished for the purpose of being made into personal ornaments.

CALAMITES, in Geology, fossil plants allied to the living horse-tail, but growing to a much larger size, which are found in the Carboniferous beds.

CALCITE (*calx*, lime: *Lat.*), a general name for mineral carbonate of lime.

CALDARIUM (*Lat.*), the hot room in Roman baths.

CALENDS (*calendæ*: *Lat.*), the first of the three periods into which the Roman month was divided. The Greeks had no calends in their month divisions; hence the Latin proverb, 'to pay at the Greek calends,' meant never to pay.

CALMS, Region of, the zone which separates the trade-winds of the two hemispheres. It alters its position a little as these winds in the course of the year change their place. In the Atlantic Ocean it has a breadth of from two to three degrees, lying a little north of the equator.

CALOYERS (*kalogeros*: *Mod. Gr.*), monks of the Greek Church.

CAMBIUM (*cambiare*, to change: *Lat.*), in Botany, the mucilaginous semi-fluid matter which is found between the bark and the wood of a tree. Delicate cells abound in it, which in the end form woody fibre or ligneous tissue. The function of cambium is to aid in the formation of new wood.

CAMORRA, a secret society in Naples which under threats of violence extorts money from persons of property, and undertakes the assassination of any one at the instance of an enemy. The members (called *camorristi*) of this dangerous society are kept under very strict discipline by the leaders. It has resisted all the efforts of the Government for many years to suppress it.

CAMPANOLOGY (*campana*, a bell: *Mediæval Lat.*), science pertaining to large bells for ringing, their proper form, materials, &c.

CAMPO SANTO (holy field: *Ital.*), the name given in Italy to a cemetery. Most of the Italian cities have large cemeteries adorned with works of sculpture. The most celebrated of the old *campi santi* is the one at Pisa. It is a small piece of ground surrounded by a high wall upon which are frescos by early masters.

CANDLE-NUT TREE, the *Aleurites triloba*, nat. order *Euphorbiaceæ*, a native of the larger Polynesian Islands. The natives of the Sandwich Islands string together the oily kernels of the nuts and burn them like a candle.

CANNA, in Botany, a genus of herbaceous plants, natives of tropical countries, belonging to the nat. order *Marantaceæ*. Having broad leaves and ornamental flowers, several species are cultivated in hot-houses. The seeds being round, hard, and black, have received the name of Indian shot. From the root stock of *Canna edulis* the starchy edible matter known as tous-les-mois is prepared.

CANON, a musical composition in which the same melody is repeated at a given distance of time in intervals of corresponding value and pitch.

CANON or **CANYON** (a great pipe, *Span.*, from *canna*, a pipe: *Lat.*), a long and very narrow ravine between high walls of rock. The cañons on the W. side of the Rocky Mountains are often of great length. The Grand Cañon of the Colorado is 550 miles long, and in one place is only 100 feet wide, whilst its depth at another is 6200 feet.

CARAGEEN, or Irish Moss, a preparation made from some sea-weeds belonging to the genus *Chondrus*. Their fronds contain a substance of a starchy nature and this being extracted by boiling, forms a jelly when cold.

CARBOLIC ACID, or Phenol, a liquid largely employed as a disinfectant. It has a very penetrating odour, and a burning taste; if swallowed, it is a violent poison. It is a little heavier than water, in which it is only slightly soluble. It is obtained by the distillation of coal-tar oil, and subsequent treatment. Its chemical constituents are carbon, hydrogen, and oxygen.

CARNIVOROUS PLANTS. The viscid glands on the leaves of the Sun dews have been mentioned under Drosera. The fact has long been known, that when flying insects settle on these leaves, they are retained by the viscid secretion, and the margins of the leaves fold over them. It is now said that the softer parts of the prey are absorbed by the plant, and digested by a secretion which acts like the gastric juice of animals. Experiments were undertaken by

Mr. F. Darwin, with a view to ascertain whether the plants were benefited by animal matter being placed on the leaves, and he came to the conclusion, that by absorbing and assimilating such matter, the plants were rendered more vigorous. He took a number of plants and carefully fed some of them by placing flies on their leaves, the others being protected from the approach of insects. The apparent result of the experiments was to show that the fed plants produced more and heavier seeds than the unfed series. The value of these experiments has, however, been called in question, and the matter cannot be said to be finally decided. [See VENUS' FLY-TRAP (*St.*).]

CARPEL (*karpos*, fruit: *Gr.*), in Botany, that part of the ovary or seed-vessel to which the ovules are attached. Theoretically the ovary is a folded leaf, and the carpel is at the introverted edges. The upper part of the leaf or prolonged midrib forms the pistil. There may be one or more carpellary leaves; in the latter case they unite to form the ovary, and the carpels are the in-turned edges.

CARPETS. Great diversity of texture is to be seen in carpets. Some show the same pattern and material on both sides with reversed colours. Others have a woollen surface on the upper side, and a rough one of hemp or flax on the under side. Some have a velvety surface with a pile or nap. Another kind is soft, with the ends of the fibres upright and half-an-inch deep. The commonest kind of carpet is the felt. This is not woven, but the wool is felted together, and the pattern printed afterwards. The simplest form of the woven carpet is that called Venetian, which is composed of a striped woollen warp on a thick woof of linen thread. The Kidderminster or Scotch carpet is so constructed as to constitute a double cloth, having two sets of worsted warp and two of woollen weft, each warp being intersected by both the wefts. It is like two pieces of cloth united surface to surface. The pattern is the same on both sides, only the colours are reversed. The Brussels carpet has a strong linen thread basis. In weaving the woollen part the threads are from time to time drawn up in loops to form the figures. In this carpet the weaver is restricted to seven colours. The Wilton carpet is nearly the same as the Brussels, except that the yarn is cut. The Turkey carpet is made entirely of wool, the long loops are cut, and the carpet is therefore very soft. Axminster carpets are not woven, but produced by hand. Each thread is knotted to the foundation, and is not connected with any other thread. This carpet is made in a frame, and to this class belong the carpets known as Velvet pile, Royal pile, and Saxony carpets. Tapestry carpets are needle-work carpets with which machinery has very little to do.

CATALAN, a native of Catalonia in Spain.

CATHETOMETER (*kathetos*, a vertical line; *metron*, a measure: *Gr.*), an instrument for determining the precise distance between two points in a vertical line.

CAUCUS, the name applied in the United States to a political meeting held as a preliminary to the legal and formal one. The course of action and main business of the party at the latter can thus be arranged beforehand.

CENTIGRADE (*centem*, a hundred; *gradus*, steps: *Lat.*), an epithet applied to anything divided into a hundred equal parts or degrees, but especially to the mercurial thermometer, when the scale between the temperatures of freezing and boiling water is so divided. This is the scale used on the Continent, and is indicated by the letter C. This scale is also called Celsius, after a professor of that name at Upsala who used it. To convert centigrade degrees into Fahrenheit, multiply the number of degrees by 9, and divide the product by 5, then add 32. To convert Fahrenheit degrees into centigrade, first subtract 32, then multiply the difference by 5, and divide the product by 9. [See THERMOMETER.]

CENTRAL POINT, in Astronomy, that point in space around which some astronomers suppose that the great system of stars—of which the solar system forms part—is moving, just as the earth moves round the sun. This point is placed somewhere in the group of the Pleiades. It has been calculated that the period of the revolution of our sun round the point in question is 18,200,000 years, and that the sun's velocity in his orbit is at the rate of 1800 miles a minute. Many years must elapse before materials can be obtained for testing the accuracy of these calculations.

CHAMFER, a term employed by carpenters and masons to signify the bevelling off of an edge so as to produce a surface inclined to the face at each side of the bevelled surface.

CHAMPAGNE WINE is produced in a district in the north-east of France occupying part of the old province of Champagne, especially in the neighbourhood of Rheims and Epernay. It is made either 'sparkling' or 'still,' that is, with or without a charge of carbonic acid gas. The former quality is produced by bottling the wine whilst its fermentation is still incomplete,—and a pressure of gas of from four to six atmospheres is allowed to remain. Hence the bottles are required to be very strong, notwithstanding which there is a considerable loss from their bursting during the manufacture.

CHAPELLE ARDENTE (*Fr.*), the hall in which the dead body of a person of high rank dying in the Roman Catholic faith lies in state. It is hung with black, is illuminated with candles, and there is a temporary altar.

CHICKEN POX, an eruptive disease of children, resembling smallpox, but of a much milder form, with less fever, more rapid progress of the eruption to maturity, and less appearance of purulence in the fluid of the vesicles.

CHILIASTS (*chilias*, a thousand: *Gr.*), believers in the near approach of the millennium.

CHINA GRASS, a plant, the *Boehmeria nivea* of botanists, belonging not to the order of grasses, but to the nat. order *Urticaceæ*. It is grown in India, China, and Japan, for the sake of the fibre, called by the Malays and the French Ramie, contained in its stems. This fibre is very strong, and besides being worked up into string fishing-nets, &c., it is so soft and fine that the Chinese make their grass cloth from it.

CHINCHILLA, a small rodent animal living in holes in the ground in the mountainous districts of Chili and Peru. The skins are largely imported into this country on account of the grey fur, of which articles of ladies' dress are made. The body of the animal is about nine inches long. The dogs with which they are hunted are trained not to injure the fur.

CHINESE LANGUAGE. This is described as language in its most archaic form; there is no alphabet, every word is a root, and every root a verb, without conjugations or inflections, or even agglutination. The adjectives are indeclinable. There are two hundred and fourteen determinatives or radical characters, which, in combination with their primitives, are exactly paralleled by (without being at all similar to) many Egyptian and Assyrian characters. Five hundred syllabic sounds are employed, which by varying their position in a sentence are made to represent thousands of distinct symbols, so that the same character may in turn play the part of verb, substantive, adjective, or adverb.

CHINOLINE, in Chemistry, a base obtained by distilling cinchonine, quinine, or strychnine with caustic potash. Its hydrochlorate has been employed as an anæsthetic. A base isomeric with this has been obtained by the destructive distillation of coal.

CHITINE (*chiton*, a skin or coat: *Gr.*), the horny material which gives strength to the integuments of crustaceous insects, and others of the lower animals. It contains nitrogen.

CHLORIMETRY, the processes by which the quantity of chlorine contained in a given weight of chloride of lime is ascertained by bleachers.

CHLORODYNE, a medicine, the ingredients of which are kept secret, but believed to be a compound of morphia, extract of Indian hemp, chloroform, and ether.

CIRCULATING DECIMAL, a decimal in which a series of digits is continually repeated. Thus, dividing unity by 7 we obtain ·142857, and if the process is continued, the same series of figures is repeated *ad infinitum*. This particular case is very remarkable, for if we multiply the series by 2, we obtain 285714; by 3, we have 428571; by 4, we have 571428, &c., and it will be found that it is possible to write down 96 digits such that their first 96 multiples consist of the same digits in the same cyclical order. It is usual to place a dot over the first and last digits of a recurring series, thus ·15723.

CIST (*cista*: *Lat.*), in Ancient Sculpture, a basket represented as carried in processions, and supposed to have reference to the mysteries of Ceres and Bacchus. Also, a round bronze box found in Etruscan tombs containing articles of a woman's toilette. Also, a sepulchral chest of stone or terra-cotta, closed at the sides and furnished with a lid.

CITRUS, in Botany, a genus of fruit trees, nat. order AURANTIACEÆ (*St.*), containing the CITRON, LEMON, LIME, ORANGE, SHADDOCK, &c. The peculiarly formed fruit, called Hesperidium by botanists, has the epicarp and mesocarp as a separable rind, whilst the endocarp divides the pulpy portion containing the seeds into three cells. The juice of these fruits contains CITRIC ACID.

CLAQUE (*Fr.*), a band of hired men (*claqueurs*) who are regularly organised under a leader, and distributed about a theatre to applaud at the proper times during the performance of a new piece on the Paris stage, as well as to stifle adverse criticism or signs of disapprobation.

CLEARING HOUSE, BANKERS', an establishment in London, at which bankers who are members daily present the cheques and bills placed in their hands for collection from other bankers. A banker, instead of sending to every bank upon which he holds cheques to collect the amount in cash, sends a clerk to the Clearing House, where the difference between the amounts of drafts in his favour and upon him is ascertained, and the balance paid by a cheque on the Bank of England. This method of transacting this part of their business saves much trouble, and obviates the risks of collecting cash. The amount transferred at the Clearing House in the course of a year is about five thousand millions of pounds sterling.

CLEISTOGAMIC (*kleistos*, locked up; *gamos*, marriage: *Gr.*), an epithet applied by botanists to flowers which are so constructed that the pollen cannot fertilise the pistil of the same flower.

CLUNIAC, an order of monks founded in A.D. 930, by Odo, abbot of a Cistercian monastery at Clugny, or Cluny, near Macon. Their house in Paris has become the Musée de Cluny.

COLOUR BLINDNESS, a not uncommon defect of the human eye, which seems usually to consist of inability to perceive the true colour of red. To persons thus affected scarlet appears as a deep dark colour, and all the compound hues into which red enters are altered. Thus orange and purple are deprived of their red component. Colour blindness with respect to green and violet also occurs, and occasionally a person is met with who is blind to all colours. When the defect is congenital there is no remedy for it. Persons employed in situations where an accurate perception of colour is needed, such as those employed on railways, or sailors, whose duty it is to be guided by signals with coloured lights, ought to undergo a careful examination with regard to this defect, for there is reason to believe that fatal accidents have been caused by the mistakes of the colour blind.

COLOURS. It is now said that it is a popular mistake to suppose that the three primary colours are red, yellow, and blue, for green ought to be substituted for yellow, as regards mixtures of lights, or combinations of colour sensations, and Professor Clerk Maxwell states that the orange and yellow of the spectrum can be exactly reproduced by mixtures of red and green.

CONSCIOUSNESS (*conscius*, knowing something along with others: *Lat.*), the faculty of knowing, the capacity of having mental impressions or feelings. It is the necessary condition of knowledge and experience, and is divisible into two departments—Object consciousness, and Subject consciousness. Everything that we can know or conceive of falls into one or other of these divisions, which comprehend the entire universe so far as we can ascertain it.

CONTRALTO (*Ital.*), or counter-tenor, a range of singing voice between the treble and the bass.

CONTRAPUNTAL (*Ital.*), what relates to the science of harmony or counterpoint.

CONVECTION OF HEAT (*convectio*, a carrying along with: *Lat.*), the diffusion of heat by the motion of the heated particles; thus when heat is applied to the bottom of a pan filled with water, the lowest strata, being first heated, ascend and diffuse heat by convection amongst the cooler water above.

COOLY (*kuli*, wages: *Tamil*), a Hindoo cultivator of the soil.

COPAL. Zanzibar copal or animi is a resin found in the earth on the east coast of Africa. It exuded from a tree called *Trachylobium Hornemannianum*, a still living species.

CORRUGATED IRON, sheet iron rolled into straight and equidistant ridges. It is employed for roofing and for the sides of temporary structures. The process gives increased strength to the material.

CORTILE (*Ital.*), the court around which a palace is built in Italy. It is often decorated on one or two stories with arcades.

COSMOS or KOSMOS (the world: *Gr.*), the order or arrangement of the universe. *Cosmical*, in opposition to Telluric, phenomena are those which show themselves beyond the bounds of the earth.

COUPLES, THEORY OF, a mathematical conception invented by Poinsot, which has proved fruitful of results in its application to the solution of problems in mechanics. A couple consists of two equal and parallel forces acting in opposite directions at the extremities of a rigid straight line. Such forces cannot be replaced by a single force (as they could in case they were acting on the line in the same direction), and it is manifest that their tendency is to produce a motion of rotation. The arm of the couple is the perpendicular distance between the lines of action of the two forces, and the moment of the couple is the product of one force by the arm. The moment expresses the power of the couple to produce rotation.

CRANIUM. [See p. 177.] There are twenty-one bones in the human skull, eight of which compose the brain capsule, and thirteen the facial portion. Where the breadth bears to the length a less proportion than 75 to 100, the skull is classed as dolicocephalous, and where the proportion is greater than 75 to 100 it is styled brachycephalous. Three distinct races of men, recognisable by their skulls, successively inhabited Europe during the Quaternary epoch. Other races may also have existed, but if so, no trace of them has hitherto been found. Anthropologists endeavour to ascertain the differences between the skulls of various races of men, the most important point being the cubic capacity of the great cavity containing the brain. Many methods have been devised, but none are entirely satisfactory. The ratio of the cubic capacity of the female skull to that of the male skull in persons of English race was found to be 854 to 1000. The average cubic capacity of the skulls of the Australian aborigines was 1283 centimetres, of the Andamanese, 1220 centimetres; Hindoos, 1306; lower grades of English, 1542; a very large but normal skull, 2075. It is generally thought that persons of high intellect have large skulls, and that the majority of criminals and persons of dull minds, have skulls of small capacity; but experience shows that large skulls do not necessarily imply vigorous understanding, and it is clear that the relations between brain capacity and mental power are rather complicated. One of the skulls of largest capacity hitherto measured belonged to a French guillotined murderer, but the size of this skull is said to have been 'evidently pathological.'

CRYPTOGAMIA (*kruptos*, secret; *gamos*, marriage: *Gr.*), in Botany, the lowest division of the vegetable kingdom, comprising ALGÆ, FUNGI, LICHENS, MOSSES, FERNS, and still more humble forms of vegetation. The plants falling into this division are destitute of flowers, and do not possess either a pistil or true pollen. Cryptogamia are thus distinguished from phanerogamous plants or those possessing stamens and pistils. Their mode of propagation is various. In some of the higher tribes there are reproductive organs known as antheridia and archegonia, the former of which emit antherozoids, and by the union of these with the archegonia, new plants are formed. Other tribes throw off little buds, each of which produces a new plant. [See HEPATICÆ (*St.*).] In the lowest tribes the propagation is by cell division. But throughout the whole series no true embryo similar to that of phanerogamous plants can be found. When spores are produced, germination takes place from any part of its surface, without the appearance of cotyledons, and hence these plants are styled acotyledonous. The majority of cryptogams are of cellular structure, but the ferns and club-mosses possess vascular bundles, and true spiral cells occur amongst the mosses. The largest terrestrial members of the cryptogamia are the Tree-ferns, some of which have trunks fifty feet high, strengthened by abundant vascular bundles.

CULTUS (*Lat.*), the worship of a Deity.

CURD, the principal constituent of milk held in solution by a slightly alkaline liquid. As thrown down in the process of cheese making by rennet or an infusion of the stomach of the calf, the coagulated matter or curd is separated from the yellowish liquid called whey. This coagulum contains the CASEIN of the milk, most of the fat, and most of the inorganic matter, chiefly phosphate of lime and sulphur, whilst the whey retains the sugar and soluble salts. [See MILK.]

CURIA, in Roman Antiquity, an edifice in which the senate held its consultations, or a place for the assembly of high councils in provincial cities; also a structure built for the religious services of the curial wards. [See p. 186.]

CYCLONIC (*kuklos*, a circle: *Gr.*), a term applied by meteorologists to a region on the earth's surface where the pressure of the atmosphere is relatively low; whilst anti-cyclonic denotes a region of relatively high pressure. The place or district where the mercury stands lower than at the places around it is the centre of a cyclonic area. On the other hand, if the mercury is higher at a given place or district than at the surrounding places, that place is the centre of an anti-cyclonic area.

CYNOCEPHALUS (*kuon*, dog; *kephale*, head: *Gr.*), a genus or tribe of large apes, containing the baboon, mandrill, and others, which have a muzzle resembling that of the dog, with a great development of the face and jaws. They live in troops, and are nearly confined to the continent of Africa. The mandrill is the largest of the tribe and is remarkable for the bright colours of its face, and the enormous protuberances of its cheeks. Figures of the dog-faced apes appear amongst the hieroglyphics on Egyptian monuments.

CYPERACEÆ, in Botany, the order of Sedges, grass-like plants divided into many genera, of which the principal are Cyperus and Carex. To the former belongs the PAPYRUS. The flowers of the Cyperaceæ are in scaly spikes, the stems are without joints, and are frequently angular. They are of very little value as fodder for cattle, but some of the species, as the Rush Nut, *Cyperus esculentus*, have tubers attached to their roots which are edible. The Cotton Grass, *Eriophorum angustifolium*, a plant growing in bogs in this country, and the Bulrush, *Scirpus lacustris*, belong to the order. Perhaps the finest species in the order is *Cyperus dives*, a native of Abyssinia, which grows to the height of nine or ten feet, and has leaves from one to two yards long.

CYPRIOTE, anything pertaining to the island of Cyprus. The ancient Cypriote inscriptions are in the Greek language, but are difficult to decipher, in consequence of having been cut in a syllabic character. Very interesting Cypriote antiquities in pottery, glass, and precious metal have been discovered.

D

DADO, in Architecture, the body of a pedestal between the base mouldings and the cornice; also any ornamental arrangement round a room on the lower part of the wall, such as wainscoting.

DAGOPAS, ancient bell-shaped buildings in Ceylon, erected to hold sacred Buddhist relics. They are often more than 200 feet high.

DAIMIOS, the great princes of Japan, who until lately had great power in the empire. A Daimio was at the head of each of the small states into which the country was divided. He levied taxes, made the law, and had his own army. There were 620 feudal nobles at that time in Japan, who had 200,000 armed retainers in their pay. When the Shogunate, or authority of the Tycoon, was abolished by the Mikado, the Daimios resigned their fiefs into his hands, and since 1871 the whole authority has been vested in the MIKADO.

DARWINISM. [See EVOLUTION and NATURAL SELECTION.]

DAVYUM, a metal discovered in 1877 by Sergius Kern in ores of platinum, and named by him after Sir Humphry Davy. It belongs to the platinum group – melts at 24° C., has a specific gravity of 9·38, and its equivalent is about 150—154.

DIFFRACTION GRATING, a plane piece of glass or speculum metal, ruled with fine parallel lines, and employed instead of a glass prism to obtain a solar spectrum by reflection. By means of a special apparatus a diffraction grating has been ruled with 17,300 lines to the inch.

DIMORPHISM (*dis*, double; *morphe*, form: *Gr.*), in Natural History, the property in a species of having two forms, *i.e.*, variations in some particulars of structure. [See PRIMULACEÆ (*St.*) for an example.]

DINOSAURIA (*deinos*, wonderful; *saura*, a lizard: *Gr.*), a group of gigantic fossil reptiles found in strata of secondary age, extending from the Lias to the Wealden. They have been divided into three families, represented by the Megalosaurus, Hyælosaurus, and Iguanodon. Their remains possess certain bird-like characters which help to bridge over the interval between the reptiles and birds.

DIOPTASE (*dia*, through; *optazein*, to see: *Gr.*), a rare mineral composed of silicate of copper found in crystals and small amorphous masses of an emerald green colour in Siberia and the Duchy of Nassau.

DIORITE (*dioros*, anything that separates: *Gr.*), in Geology, an igneous rock, often found as a dividing dyke, composed essentially of hornblende, amphibole, and Labrador felspar. It has a granular texture.

DISCOBOLUS (*discobolos*, a quoit player: *Gr.*), in ancient Art, the statue of a man in the act of flinging a quoit. The ancient Greek sculptor, Myron, was celebrated for his Discoboli.

DOLDRUMS, the name given by sailors to the region of CALMS (*St.*) at the equator.

DOLERITE, a variety of basalt with a crystalline and vitreous fracture. It is composed of augite and Labrador felspar.

DOLMEN, in Archæology, a prehistoric tomb made of two large slabs of stone set opposite to one another on edge, with a third slab laid flat on the top. Such rude structures were formerly called Druid's altars. If there is only a single upright stone supporting one end of the capstone whilst the other rests on the ground, this has been styled a demi-dolmen.

DOSSAL (*dos*, the back: *Fr.*), a screen of ornamental wood-work, or the decorated back of an altar or chair. In the case of an altar it is sometimes covered with embroidery or tapestry.

DURIAN (*duri*, a spine: *Malay*), the fruit of a tall tree, *Durio zibethinus*, nat. order *Sterculiaceæ*, growing on the Malay peninsula, in Borneo, and other islands. The leathery skin, covered with spines, encloses a straw-coloured custard-like pulp in which large seeds are embedded. Those who live on the spot think the fruit extremely delicious, but persons who taste it for the first time are offended with its disagreeable smell. A. R. Wallace declares that it affords 'a new sensation worth a journey to the East to experience;' and another traveller speaks of it as the best of all fruits with the worst of characters.

DYNAMITE (*dunamis*, force: *Gr.*), is a mechanical mixture of NITRO-GLYCERINE (*St.*) with matters in the state of powder, such as infusorial earth, chalk, &c. It has a high explosive power, about four times that of gunpowder. It is much safer to handle and transport than nitro-glycerine, but still very great care has to be exercised in its management. When employed for blasting purposes it is usually exploded by means of a copper cap containing a few grains of a fulminate, and this is fired by a fuse or by an electric wire. [See TORPEDO (*St.*).]

E

EBIONITES, a sect of Jews who, whilst maintaining that Christ was a man inspired by God to declare his will, insisted upon the obligation of the Law. They are supposed to have lived in the second century.

EBONITE. [See CAOUTCHOUC.]

ECHIDNA (*Gr.*), a genus of monotreme animals living in Australia, of which only one species, *E. hystrix*, is known. It is two or three times larger than our hedgehog. The back is covered with spines, and it can roll itself up as a ball like a hedgehog. The mouth is furnished with a beak. The legs are short, and have clawed feet, fitted for digging. Its habits are sluggish, spending the greater part of its life in its burrow. Ants are its principal food.

EDELWEISS (*edel*, precious; *weiss*, white: *Ger.*), an interesting plant covered with white down, growing on the mountains of Central Europe. It is the *Leontopodium alpinum* (or *Gnaphalium leontopodium*) of botanists, nat. order *Compositæ*, and may be classed amongst the Everlastings. There has been such a reckless destruction of this somewhat rare plant by the natives of some parts of the Alps for the purpose of selling it to strangers, that a fine has been imposed upon every one selling it in the living state.

EDENTATA (*e*, without; *dentes*, teeth: *Lat.*), a name not very happily chosen for an order of mammals, seeing that several of the animals belonging to it possess teeth. The ant-eaters, sloths, and the monotremes of Australia are placed here. Teeth when present are never incisive, and are always one-fanged.

EDITIO PRINCEPS, in Bibliography, the finest edition of an old author's works.

EFFENDI, amongst the Turks, a title given to official persons and those of some position. The minister of foreign affairs at the Porte is styled Reis-Effendi.

ELAND, one of the antelopes of the Cape of Good Hope; the *Oreus canna* of zoologists. It is about five feet high and eight feet long. It has been introduced into some English parks, as it stands our climate well. The flesh is much prized by the colonists.

ELECTRIC LIGHT. [See p. 239.] The application of electricity for the purpose of obtaining a light which should supersede lighting by gas is a problem the solution of which has been frequently attempted. In the session of 1879 the House of Commons appointed a committee to consider certain questions connected with this subject, and as their report gives an interesting summary of the present position of the matter, the following passages are printed here:—'It is an evolution of scientific discovery which has been in active progress during the whole of this century. Essentially the electric light is produced by the transformation of energy either through chemical or mechanical means. The energy may be derived from a natural force, as, for instance, a waterfall, or through combustion of a material in the cells of a voltaic battery, or of fuel in a furnace. The energy being converted into an electric current, may be used to manifest electric light by passing between carbon points or by rendering incandescent solid bodies, such as iridium. A remarkable feature of the electric light is that it produces a transformation of energy in a singularly complete manner. Thus the energy of one horse-power may be converted into gaslight, and yields a luminosity equal to 12 candle-power. But the same amount of energy transformed into electric light produces 1600 candle-power. It is not, therefore, surprising that while many practical witnesses see serious difficulties in the speedy adaptation of the electric light to useful purposes of illumination, the scientific witnesses see in this economy of force the means of great industrial development, and believe that in the future it is destined to take a leading part in public and private illumination. There is one point on which all witnesses concurred, that its use would produce little of that vitiated air which is largely formed by the products of combustion of ordinary illuminants. Scientific witnesses also considered that in the future the electric current might be extensively used to transmit power as well as light to considerable distances, so that the power applied to mechanical purposes during the day might be made available for light during the night. So far as the practical application of the electric light has already gone, there seems to be no reason to doubt that it has established itself for lighthouse illumination, and is fitted to illumine large symmetrical places, such as squares, public halls, railway stations, and workshops. It is used in Paris for lighting shops which require a light by which different colours may be distinguished, and has recently been used in England for the same purpose with satisfactory results. Many trials have been made for street illumination with greater or less success. Compared with gas, the economy for equal illumination does not yet appear to be conclusively established. Although in some cases the relative economy for equal candle-power is on the side of the electric light, yet in other cases gas illumination of equal intensity has the advantage. Unquestionably the electric light has not made that progress which would enable it in its present condition to enter into general competition with gas for the ordinary purposes of domestic supply. In large establishments the motors necessary to produce the electric light may be readily provided, but, so far as we have received evidence, no system of central origin and distribution suitable to houses of moderate size has hitherto been established.'

ELECTRIC TELEGRAPH. One of the recent inventions connected with this subject is Cowper's Writing Telegraph. This consists of a combined transmitting and receiving instrument at each station, so that messages can be sent in either direction. The principle of the invention is described to be the communicating to a writing pen placed on the recording instrument the exact position of a pencil used by the operator at the transmitting instrument by means of two line wires, the vertical position of the pencil being communicated by one, and its horizontal position by the other. Each of these wires actuates its own needle, and these needles are so arranged that they actuate a writing pen to which ink is constantly supplied. The pen moves up or down, backwards or forwards, in exact obedience to the motions of the pencil, which is guided by the operator at the transmitting instrument. The message is written by the sender on a strip or riband of paper which passes under his hand, being unwound by clockwork. The message is produced by the pen at the receiving station on a slightly smaller scale than in the pencil original, but in other respects in precisely the same characters and style of handwriting, upon a similar riband of paper moved under the pen by clockwork. The message, when completed at the receiving station, is cut off and sent to its destination, whilst that at the transmitting end can be preserved as a record.

ELECTRODES (*odos*, a path: *Gr.*), the poles of a galvanic battery. Faraday termed the positive pole the *anode* (*ana*, through: *Gr.*), and the negative pole the *cathode* (*kata*, in opposition to: *Gr.*). In a cell of zinc and copper, for example, the copper plate forms the anode, the zinc plate the cathode. If the currents are conveyed by wires out of the battery, the terminals of the wires form the electrodes.

ELECTROLYTE, the substance decomposed or electrolysed in the process of ELECTROLYSIS. [See p. 241.]

ELECTROPLATING, ELECTRO-GILDING, a process for covering an article formed of some common metal with a thin coat of silver or gold. This is an example of ELECTROLYSIS, a salt of one of the precious metals being decomposed by the action of a galvanic battery. The article intended to be coated is made the negative ELECTRODE (*St.*), and a plate of silver or gold forms the positive electrode. Both electrodes are immersed in a bath consisting of a solution of the salt, and the precious metal is deposited upon the article as the salt undergoes decomposition on the passage of an electrical current.

ELEMENTARY BODIES. Chemists now teach that what are commonly styled elements are not necessarily simple bodies, but only bodies which have not hitherto been decomposed. Mr. Lockyer states that some of them, when examined spectroscopically, exhibit phenomena which lend support to the hypothesis that they are compound. The following new elements have been added of late years to the list given on p. 259. Like Cæsium, Rubidium, Thallium and Indium, they have been discovered by the method of spectrum analysis.

	Equiv	*Sp. Grav.*
Davyum . .	150–154	9·38
Decipium . .	106	...
Philippium . .	74	...
Norwegium . .	145	9·44
Samarium . .	...	...

ELVAN, the Cornish name of a granitic porphyry appearing in the form of dykes.

EMERITUS (one who has served out his time: *Lat.*), a term often applied to retired professors in a university.

EMISSARY (*emissarium*: *Lat.*), the outlet or drain of a lake.

EMPIRICISM (*empeirikos*, experimental: *Gr.*), in Philosophy, the doctrine that all our knowledge is entirely derived from experience.

ENCEPHALON (*en*, in; *kephalaion*, the head: *Gr.*), the contents of the head, namely, the brain.

ENCHORIAL. [See HIEROGLYPHICS.]

ENCYCLIC LETTER (*kuklikos*, circular: *Gr.*), a term usually applied to the letters which the Pope sends to all the bishops on matters affecting the whole Church.

ENDOCHROME (*endon*, within; *chroma*, colour: *Gr.*), in Botany, the contents of the cells in the order of Algæ. The matter is frequently coloured.

EPIGRAPHY (*epi*, upon; *graphe*, writing: *Gr.*), the study of ancient inscriptions or epigrammata.

EPITHEMIUM (*epithema*, a cover: *Gr.*), a term applied by anatomists to the lining of the internal cavities of the body. It consists of cells of various forms in different parts so connected as to form a delicate membrane answering to the skin of the outer surface of the body. The epithelial cells of the respiratory tract and some other parts carry minute hair-like appendages called cilia.

EPONYM (*eponumos*, an epithet for that which gives its name to something: *Gr.*). In ancient Athens the first of the annually elected archons gave his name to his year of office, and he was therefore styled the eponymous archon. A great number of inscriptions lately discovered amongst Assyrian ruins are dated with the name of an officer called *limu*, who held office for a year. Hence the records thus dated are styled eponymous.

EQUATORIAL INSTRUMENT, in Astronomical Observatories, a telescope mounted in such a way as to be capable of motion in two planes at right angles to each other, the amount of angular motion in each being measured in two circles coordinate to each other, whose planes are parallel to those on which the telescope moves. The principal axis of the mounting is made parallel to the earth's axis, and therefore points to the poles of the heavens. The plane of one of the circles is thus parallel to the earth's equator, and by its divisions can be measured hour angles or differences of right ascension. The telescope is attached to the other circle, which being made to rotate round the principal axis of the mounting, will correspond in its various positions to great circles in the heavens. These being hour circles, declinations or polar distances or their differences can be measured by the graduated circle.

EQUILIBRIUM. A body resting on a horizontal plane is in a state of equilibrium when the vertical through the centre of gravity falls within the figure drawn through its points of support. If a body is capable of turning about an axis or a fixed point, the equilibrium is said to be stable when the centre of gravity is below, and unstable when the centre of gravity is above, the axis or point of suspension. In the case of a body resting on a horizontal plane, which it touches only at one point, thus to ensure equilibrium, it is necessary that the vertical through the centre of gravity should meet the plane at the point of contact, and to ensure stable equilibrium, it is necessary that the centre of gravity should occupy the lowest possible position.

ERASTIAN, a term applied to those persons who think that the Church should be under the control of the State. Erastus was a German divine, born 1524, who taught that the punishment for offences whether civil or religious, should be awarded and carried out by the civil magistrate.

EROSION (*erosio*, an eating away: *Lat.*), a term applied by geologists to the destruction of land near a river by the flowing water, or to that of a coast by the sea, or to the waste of land by rain. Valleys of erosion are those that have been formed by running water.

ERRATIC BLOCKS, in Geology, are blocks of stone which have been brought from a distance by natural causes, and deposited on the surface of a country. The structure of the stone frequently enables an observer to discover the spot whence they have been transported, sometimes hundreds of miles distant. The agency of transport is supposed to have been in some cases glaciers, at others floating ice when the land was at a lower level than at the present day.

ESCHATOLOGY (*eschatos*, the last; *logos*, a discourse: *Gr.*), in Theology, the doctrine concerning the resurrection, final judgment, and what are called the last things.

EVOLUTION, in Natural History, the doctrine which teaches that all existing forms of organised beings, both vegetable and animal, have been gradually developed from simpler forms through the ages of the past. Lamarck and others put forward doctrines of this nature, but the form in which it is now widely accepted is due to Mr. Darwin.

EX VOTO (according to a vow: *Lat.*), an offering made by a grateful devotee for restoration from sickness or preservation from danger. In ancient times the temples of the gods were hung with offerings which took various shapes, legs, arms, ears, &c., in terra-cotta or other material, just as at this day may be seen the wax models and pictures round the altars of popular saints in Roman Catholic countries.

F

FALUNS, a name given to beds of sand and marl containing fossil shells and corals, found in patches in the north-west of France (Dinan, Nantes, Tours). About two-thirds of the shells are extinct, and these beds have therefore been assigned to the Miocene Tertiary epoch. Remains of mastodon, rhinoceros, hippopotamus, and other terrestrial quadrupeds, as well as of cetacea, are here and there intermixed. The name Faluns has passed into geology.

FAYENCE (*Fr.*), a general name given to ornamental pottery excluding porcelain, but rather loosely employed. The name is derived from the town of Faenza, in Italy, once celebrated for its manufacture of fine earthenware.

FELLAH, *pl.* FELLAHIN (a cultivator of the soil: *Arabic*), the peasants of the Nile valley, the descendants of the ancient Egyptians; and their language, the Coptic, is the modern form of the old Egyptian. They strikingly resemble the figures on the old monuments.

FETISHISM (*feitico*, sorcery: *Port.*), that primitive belief which assigns consciousness and volition to all objects that come into contact with human sense. Trees, stones, mountains, sun, moon, and stars are endowed in man's ignorance with those attributes of life and thought which he feels within himself, and some of them, in obedience to his superstitious tendencies, are selected for rude worship.

FERNS, TREE [See p. 279.] More than 200 species of tree ferns are known to botanists, who distribute them among many genera Some species attain the height of fifty feet, with a trunk having a thickness of one foot. Others do not exceed the height of three or four feet, with a trunk one inch thick The real diameter of the trunk is often much increased by the bases of dead leaf stalks (stipes), and by a matted mass of aerial roots. They are widely distributed either on mountains within the tropics, or in the extra tropical islands of the southern hemisphere. Tree ferns are of little use to man. In the Sandwich Islands are some species of *Cibotium* which have the bases of their leaf stalks clothed with an abundance of delicate brown silky hairs This is gathered and exported to California, where it is employed as a material for stuffing cushions The BAROMETZ or Vegetable Lamb of fable, is the decumbent stem of a tree fern, *Cibotium barometz*, which is densely clothed with silky hairs Several species of tree ferns are cultivated in the conservatories of this country, belonging principally to the genera *Alsophila*, *Cyathea*, and *Dicksonia*.

FEZ a tall red hat without a brim, worn by the Turks. It is so called from Fez, in Morocco, one of the places of its manufacture.

FILARIA (*filum*, a thread· *Lat*), a genus of Nematoid worms with long filiform bodies. Two species occur under the leaves of plants growing in fresh water. Another species is the Guinea worm which infests the natives of Africa, Arabia, and India. It penetrates the skin and raises a tumour. Other species have been found in the bronchial tubes of man, the lachrymal gland, and the eye; even in the blood of man there has been detected a very minute species.

FILAR MICROMETER, a micrometer for an astronomical telescope formed of very fine wires, or of the most delicate spider's threads (*fila*. *Lat.*) that can be procured.

FINIAL (*finis*, the end: *Lat.*), in Architecture, the terminating ornament of a pinacle, canopy, &c

FLAMBOYANT STYLE, in Architecture, the highly decorated style of Gothic which prevailed in France at the time the PERPENDICULAR was practised in England. The tracery of the windows, panels, &c., is wavy, and the ornamentation lavish. The French word *flamboyant* signifies flaming.

FLAX, NEW ZEALAND, the *Phormium tenax* of botanists, nat. order *Liliaceæ*. This handsome plant is quite different in appearance and natural position from the common flax plant of Europe Its flat leaves, which grow directly from the root, are from five to ten feet long, and three inches broad. They abound with long fibres, affording good material for cordage, as well as a finer material for textile manufactures The principal difficulty in their preparation arises from their gummy juice. The plants form large tufts, and afforded excellent hiding places for the Maoris when they were at war with the colonists.

FLUORESCENCE. When certain bodies (for example, a solution of sulphate of quinine) are viewed by transmitted light, they appear colourless, but when viewed in reflected light they have a peculiar self luminous appearance. This property has been termed fluorescence, as it was first observed in fluor spar. The property is well seen in canary glass coloured with oxide of uranium, when placed in the ultra-violet portion of the solar spectrum Fluorescence is believed to be essentially identical with phosphorescence. Many bodies have been found to possess the power of absorbing dark rays of high refrangibility, and of emitting them as luminous rays of lower refrangibility, or, as it has been said, of absorbing darkness and of giving it forth as light. Thus, if certain substances are subjected to the action of the invisible ultra-violet rays of the solar spectrum, they become luminous.

FLY WHEEL, in machinery, a large wheel with a heavy rim attached to the shaft of a steam-engine for the purpose of rendering the motion uniform. This it effects by absorbing the surplus force at one part of the action and giving it out when the action is deficient, the 'dead points' being thus nullified.

FOG HORN, an instrument for sending a sound to a considerable distance through a fog for the purpose of warning against danger Experiments have shown that whistles and bells are not sufficiently effective. Sound reflectors are of little value because the rays of sound do not, like those of light, move parallel to each other from the surface of a concave reflector, but constantly diverge laterally to all sides, and although at first the sound is more intense in the axis of the reflector, it finally spreads out in all directions. It has been found that fog signals can be best transmitted by horns constructed on the principle of the REED PIPE, the sound of which can be heard at a distance of three miles.

FOLK-LORE, a term applied to a collection of local traditions, superstitions, legendary stories and ballads, proverbial sayings, old customs, and other kindred matters exemplifying the ideas, impressions, and tastes prevalent among the common people Scientifically treated the study of folk lore is a branch of anthropology There is a Folk Lore Society in London

FOLLICLE (*folliculus* a little bag *Lat*) in Botany, an elongate seed vessel something like a pod containing several seeds and opening by the ventral suture whereas the pod opens both dorsally and ventrally The seed vessels of the lark spur and hellebore are follicles

FOOT POUND, the unit measure in this country of mechanical work Thus 100 foot pounds of work signifies that an effort has been exerted equivalent to raising 100 pounds one foot high or one pound 100 feet high The unit measure in France is the mètre kilogramme

FRIGIDARIUM (*Lat*) the room in a Roman bath where the bathers remained to cool themselves after having had a hot bath

FRONDE, the name of a party in France, which, during the minority of Louis XIV, opposed the absolutist politics of Cardinal Mazarin and caused great disturbances (1648 1652) It was headed by the great nobility and the Parliament later by the Prince de Condé The term is derived from the French word *fronder*, to blame, to ridicule

FUEROS (*Spanish*), the old privileges of the two Spanish provinces, Biscay and Navarre lately abolished They consisted chiefly of a special exemption from the duty of contributing soldiers for the defence of the kingdom, and from all except local taxation

FULGURITE (*fulgur* lightning *Lat*), a tube formed by lightning when it strikes a mass of sand The walls are of vitrified sand A fulgurite is usually sinuous and branched, and it ends in a point

G

GALLIUM (*Gallia*, France *Lat*) a silvery white metal discovered in 1875 by Lecoq de Boisbaudran existing in minute quantities amongst zinc ore obtained in the Pyrenees It is hard, slightly malleable but very fusible, melting with the heat of the hand at 86° F When once melted at that temperature it may be cooled down to the freezing point of water without solidifying and may be kept in the liquid state for several months The two states form a hydro electric couple, the solid metal being the positive element Its specific gravity is 4 7 its equivalent 69 8

GAMBIER, or *Terra Japonica* a brown substance used for tanning and dyeing purposes, like Cutch or Catechu, and imported from the Straits of Malacca It is obtained from a climbing shrub the *Uncaria Gambir* of botanists (nat order *Cinchonaceae*) by boiling the leaves and young shoots The plant has hooked spines and its name is derived from the Latin word *uncus* a hook

GANISTER, the Yorkshire name of the lower coal measures They contain beds of a fire clay which is largely employed as a material for lining iron smelting furnaces which material has also received the name of ganister

GARGOYLE or **GURGOYLE**, in Gothic Architecture, a projecting spout to throw off water from a roof It is often carved into a grotesque form, such as the gaping head of a man or animal, hence the name through the French *gargouille* a spout, from *gurgulio* the throat *Lat*

GASES LIQUEFACTION OF Up to the year 1878 all the gaseous forms of matter had been reduced to a liquid state except only oxygen nitrogen and hydrogen which had resisted all attempts to liquefy them and hence had acquired the name of permanent gases But in December of that year M Raoul Pictet of Geneva and M Cailletet of Paris succeeded in showing that they also might be liquefied By applying a pressure of from 200 to 280 atmospheres and at the same time reducing the temperature to 300° C below zero each gas was separately liquefied (hydrogen, however, only showing itself as a vapoury cloud) and then atmospheric air (a mixture of oxygen and nitrogen) was also brought to a liquid state by similar treatment If a suitable degree of pressure and cold could be applied no doubt these gases would be made to appear as solids although this may never be actually done

GASTEROPODA (*gaster* belly *pous*, foot *Gr*) the typical class of the Mollusca including land and sea snails, whelks limpets &c They exhibit considerable variety of form some being coiled into a spiral others of an elongate shape but nearly all crawl on a flat disc on the under side of the body called a foot Some are protected by shells, others are destitute of shells The great majority of the univalve shells in the cabinet of conchologists have belonged to

Gasteropoda. There are two natural groups, in one of which the animals breathe air, in the other aërated water, the latter undergoing a metamorphosis in the young state, whilst the water breathers have always the same shape.

GASTRÆA. A theory has been propounded by Professor Haeckel as to a primitive animal form called by him Gastræa (*gaster*, a stomach: *Gr.*), from which all animals higher than the PROTOZOA are supposed to have descended. By the repeated division of the original germ cell a layer of cells resulted which took the shape of a round ball filled with liquid. A depression showed itself at one point, which gradually deepened until one half the ball was inverted inside the other, the mouth of the cup or hollow thus formed being narrowed so that there was now another ball of two layers of cells with an orifice leading into the interior stomach. This is the *gastrula* (a little stomach), which, being furnished with vibratile hairs and other appendages, constitutes the gastræa or primitive intestinal animal. From this simple form developed in one direction the zoophytes, in another the worms, and from the latter the vertebrate class ultimately proceeded.

GATLING GUN, a gun with several barrels, and furnished with a rotating drum, by means of which it can be rapidly loaded and discharged, so that a great number of shots can be fired in a minute.

GERM THEORY of Disease. [See BACTERIA (*S.*).]

GESTA (achievements: *Lat.*), a word employed by mediæval writers in describing the exploits of warriors, knights errant, and other worthies. In English it became Gestes, which was used in opposition to the Dictes or Seyinges of the Philosophres.

GRAAL, THE HOLY, a superstition of the Middle Ages relating to the cup (*grasal: Old French*) from which the Son of Man drank at the Last Supper. This, it was said, was filled by Joseph of Arimathea with the blood that flowed from His wounds, and thereby acquired miraculous virtues. The Sangreal was then lost, and the search for it was undertaken by the Knights of the Round Table. It was found by Perceval, and at his death was carried up to heaven.

GRASSES. [See p. 326.] To this family belong the Pampas Grass (*Gynerium argenteum*), much cultivated in English gardens on account of its large handsome spikes of silvery flowers; the Guinea Grass (*Panicum maximum*), which grows in tufts, and is sometimes cultivated for fodder; the Canary Grass (*Phalaris Canariensis*), cultivated for its seeds, the food of cage birds; Tussac Grass (*Dactylis cespitosa*), a native of the Falkland Islands. The BAMBOOS are gigantic species of this family.

GREGORIAN CHANT, plain chant or plain song, the few notes to which the words of the Liturgies are recited in Roman Catholic Churches. Something of the sort was very early in use by ecclesiastics, but it took the name of St. Gregory from his having compiled from existing chants a ritual book of music or antiphonarium.

GUAIACUM, the name of a resin often called Gum Guaiacum, employed in pharmacy and obtained from a tree growing in the West Indies, *Guaiacum officinale*, nat. order *Zygophyllaceæ*. The wood of this tree is so hard and heavy that it sinks in water. It is imported into this country under the name of Brazil Wood and Lignum Vitæ, being in request for articles of turnery.

GUN COTTON, a preparation of cotton which has come into use of late years as a substitute for gunpowder for explosive purposes. Its properties were discovered by Schoenbein, the chemist of Basle, in 1846. It is prepared by steeping cotton in a mixture of sulphuric and nitric acids. It is then washed, and treated so as to get rid of the acids. When dried it is ready for use. The greatest care must be taken in preparing and storing it, and even then disastrous explosions have occurred. Gun cotton explodes at a temperature of 277° F.; percussion will also cause it to explode. Its combustion takes place with great rapidity, and its propelling power is three times that of gunpowder, weight for weight. Collodion is made from gun cotton by dissolving it in a mixture of alcohol and ether.

GUTTÆ (drops: *Lat.*), in Architecture, ornaments shaped something like drops placed below the triglyphs of the frieze in the Doric order.

GYMNASIUM (*gumnasion: Gr.*). In Germany and France the higher schools for boys before proceeding to the universities are styled gymnasia and gymnases.

H

HÆMOPTYSIS (*aima*, blood; *ptusis*, a spitting: *Gr.*), the coughing up of blood from the lungs, a symptom which should induce the patient to seek the advice of a medical man at once.

HALTERES, in Entomology, two small appendages, one attached at each side of the metathorax, behind the wings in insects of the order Diptera. They may be plainly seen in the common housefly.

They vary a good deal in form and their use is not well known, their name is taken from the Latin word *halteres*, the pieces of load which a person carried in his hands to balance himself when performing gymnastic exercises

HAMITIC (Ham, the son of Noah), a term applied to the ancient Egyptian, the modern form of it called Coptic, and other kindred African languages

HANAP (*hnæp*. *Ang Sax*), a cup or goblet

HARA KIRU, the Japanese punishment, which a condemned man carries out by ripping himself up with a knife

HARMONIUM a musical instrument with a keyboard like that of a pianoforte The sounds are produced not by a hammer striking upon wires but by wind from a bellows worked by the feet driven through REED PIPES (*St*)

HARMONY PRE ESTABLISHED a theory put forward by the German philosopher Leibnitz, to explain the apparent action of body upon mind in the individual It was laid down as an axiom that only like could act upon like, and as body and mind are unlike, it was asked, how did the former act on the latter? Leibnitz answered that the human body and the human mind are independent, but corresponding machines They were adjusted as two separate clocks may be, one to strike the hour, and the other to point to it

HEDONISM (*hedone* pleasure *Gr*), the doctrine that the great aim of life is to seek pleasurable emotions and avoid painful ones

HEGEMONY (*hegemonia* *Gr*) the supremacy conferred on one of several States of ancient Greece when confederated for war In modern Germany hegemony is enjoyed by Prussia

HELIOGRAPH (*helios*, the sun *graphein* to write *Gr*), an apparatus for transmitting signals by the reflection of the suns rays It consists of a mirror adjusted to mechanism, which causes the reflected rays to continue to reach the same distant point notwithstanding the suns motion By pressing a key the flashes can be made to differ in duration so as to indicate letters or words according to a given code Signals, it is said, can be read by it as far as 80 or 100 miles

HELIOGRAPHIC POSITION in Astronomy, the solar latitude and longitude of an object seen on the suns face

HELIOSTAT (*helios*, the sun *states* standing *Gr*) an apparatus consisting of a mirror made to reflect the suns rays to a distant point and worked in connection with a combination of telescopes It is employed in surveying for the purpose of laying down angles Triangles with sides of more than 100 miles in length, have been accurately laid down by its aid.

HELIOTROPE (*helios*, the sun, *trophe*, a turning *Gr*) in Surveying, an instrument for reflecting a ray of light from one station to another

HELIX (a whorl *Gr*), in Electrical Science a coil of insulated copper wire enveloping a magnet or iron core

HENRI DEUX WARE a white earthenware of great rarity made in France in the time of Henry II Its slight ornamentation was produced by indenting the soft paste with an iron tool and filling the indents with paste of a different colour

HEPATICÆ (*hepar*, the liver *Lat*), in Botany, a group of cryptogamous plants containing several tribes or orders The best known plants are called Liverworts and have broad fronds which creep on the ground in damp places Others, more like mosses, are found on rocks and trees Besides propagation by antheridia (with antherozoids), and archegonia, several species throw off little green buds each of which will produce a plant Hepaticæ are of no known use, though formerly some of the liverwort section were administered in cases of liver disease.

HERMÆ in Ancient Sculpture, short angular pillars with a head at the top They were set up at the sides of roads and derived their designation from the god Hermes the Mercury of the Romans, whose bust was frequently upon them

HERRING [See p 348] This fish is found in four conditions —(1) the fry or sill (2) maties or fat herring, (3) the full herring (4) the shotten or spent herring Yarrell thought that the fish takes about eighteen months to reach its full size and maturity but it is probable that it reaches its spawning condition in about a year that the eggs are hatched in two or three weeks after they have been deposited and that in six or seven weeks they have attained three inches in length The maties or fat herring become full herrings in three or four months The full herring appears at first here and there among the shoals but gradually increases in number until it largely preponderates over the maties The herrings then collect in prodigious numbers, in places suitable for the deposit of the spawn Here they lie in tiers covering several square miles of sea bottom After spawning they withdraw as spent herrings into deep water There are two spawning seasons the spring (February and March), and autumn (August and September), but it is not likely that the same fish spawns twice a year and it is thought more probable that the spring and autumn shoals are distinct The food of the herring consists of small crustacea and small fish. In the matie or fat condition they feed voraciously The herring has many enemies both amongst its own class and birds. It is calculated that our fishermen take annually 900,000,000, but this number is insignificant compared with that destroyed by the cod and other fishes. It is not uncommon to capture a cod with six or seven herrings in its stomach. Gulls and gannets destroy them by millions.

HERRING BONE WORK, in Mediæval Architecture, masonry or brick work, where the materials were placed angularly instead of flat.

HESPERIDES, in Grecian Mythology, the female guardians of the golden apples given by the Earth to Hera (Juno) on her marriage with Zeus (Jupiter). Different accounts are given as to their number (from three to seven), and as to their parentage, but they derive their name from their supposed mother, Hesperis. Their beautiful garden was placed on Mount Atlas or somewhere in Libya, *i.e.*, North Africa, where they were assisted in their duties by a dragon, which was killed by Hercules when he took possession of the apples.

HEXAPLA (*hexaploos*, six fold: *Gr.*), a work in six languages, especially the Bible when six versions are printed side by side.

HIERATIC (*hieratikos*, sacerdotal: *Gr.*), the character which the ancient Egyptians employed in writing on papyrus, and which may be styled cursive hieroglyphics. Vast numbers of papyri with such writing have been discovered relating to a great variety of topics, fiction, history, scientific and medical treatises, religion, legal proceedings, &c. The style is diffuse, and the characters differ a good deal.

HIMYARITIC INSCRIPTIONS. The Himyarites were a Semitic race who, in the second century of our era, established a powerful state in Southern Arabia (Yemen), but who were overpowered by the Mohammedan Arabs in the eighth century. Inscriptions by them, some of which scholars have deciphered, have been found on rocks and copper plates.

HIPPURITIC LIMESTONE, in Geology, a deposit belonging to the lower division of the Cretaceous epoch, found in the South of Europe, and characterised by extinct shells of a peculiar form belonging to the genera Hippurites, Radiolites, &c.

HONEY GUIDE, a bird belonging to the genus *Indicator*, or the Cuckoo family, which lives in South Africa, and has the habit of guiding the Hottentots to the nests of wild bees by flitting before them and repeating a peculiar cry. The natives have great esteem for their feathered friends, and always leave them a portion of honey as their share of the spoil. — Several species of birds belonging to the order of Passeres have received the name of Honey Suckers from their feeding upon the nectar secreted by flowers. They are found in Australia, the Indian Archipelago and Africa.

HOSPODAR. [See p. 356.] This title has been abandoned, Moldavia and Wallachia having in 1862 united and formed a country called Roumania, under the rule of a prince. With the assistance of Russia the country has thrown off the suzerainty of Turkey and become completely independent.

HOVAS, the principal race in Madagascar. They are of Malayo Polynesian origin, as their physical conformation and language show.

HYDRAULIC MINING, sometimes called Gulch or Placer Mining. In the state of California are thick deposits of gravel and sand, through which particles of gold are disseminated. These are extracted by the following process. A supply of water with head pressure is obtained, and this is made to play through pipes fitted with nozzles upon the vertical or sloping face of the deposit. The gravel is thus washed down into a long sluice through which the water drives it whilst the gold is deposited on the way. In drift mining, which is also carried on in similar deposits, the gravel is dug out with shovels and carried on trucks to a sluice through which water flows and the gold falls out in the course.

HYDROZOA (*hudor*, water; *zoon*, animal: *Gr.*), an order of Zoophytes, usually compound, and living in both fresh and salt water. The compound hydrozoa generally form a polypary, a delicate horny or glass stalk with cups, in each of which lives a single polyp connected by a fleshy thread with the other polyps in the polypary. The polyps can protrude themselves out of the cups or withdraw within, and are usually furnished with tentacles variously disposed. Polyparies of various species are to be seen on every coast resembling patches of whitish moss. The species of Hydra, common in fresh water, attached to plants, has no polypary. It is a minute animal, and an interesting object when living for the microscope.

HYOID BONE, in Anatomy, a bone placed between the root of the tongue and the larynx. It is so called from its shape resembling that of the Greek letter *v*.

HYPÆTHRAL (*hupo*, beneath; *aither*, the air: *Gr.*), in Ancient Architecture, a term applied to those temples which had their cellæ not covered in but exposed to the sky.

HYPOCAUST (*hypocaustum*: *Lat.*), a room in a Roman bath which was heated by a fire underneath the floor.

I

ICON or **IKON** (*eikon*, a representation: *Gr.*). In Russia, a picture or low relief of a saint is placed in almost every room of the houses to stimulate the devotional feelings of the inhabitants. A traveller states that in the ante-chambers of the Exchange at St. Petersburg large pictures are hung up, with lamps suspended in front of them, and before these merchants perform their devotions as they come in or go away. Icons are to be found everywhere, in the public offices, the palaces, museums, railway stations, shops, even in the cabins of ships, and the icon, wherever it may be, is respected.

IDENTITY, sameness, not merely similarity. Memory is the basis of all evidence of identity. We must remember the former appearance and properties of an object before we can say that the one before us is the same. As to Personal Identity the remembrance of former actions, feelings, and thoughts, is the chain by which our present and our past selves are connected into a whole, which has endured with unbroken continuity from moment to moment, from day to day, and from year to year, ever since we possessed consciousness.

INDIANS (*Indiani: Lat.*), the inhabitants of India, a country deriving its name from the river Indus. When America was discovered, the Spaniards, supposing that they had reached the east coast of India, called the natives Indians, and this erroneous name has been perpetuated. Hence also the names of East Indies and West Indies. The American Indians are of the Mongolian race. They are divided into numerous tribes and speak a great variety of tongues or dialects. They are estimated to be about 12,150,000 in number, of which 330,000 live in the United States.

INDIAN SUMMER, a name given in the United States to the mild and serene weather enjoyed in the month of October.

INDICATOR, in Mechanics, an apparatus for showing the pressure of the steam in the cylinder of a steam engine, and for marking its indications on paper, from which can be seen the varying pressure throughout the stroke of the piston.

INDIUM, a soft white metal not tarnishing in the air, discovered in German ores of zinc (blende). It is of rare occurrence, melts at 351.5° F., has a specific gravity of 7.36; chemical equivalent, 75.6.

INDRA, the conqueror, a Hindoo deity; at the period of the Vedas the highest deity, the chief of the gods of the air, but afterwards chief of the nether deities.

IN PARTIBUS INFIDELIUM (in heathen parts: *Lat.*). Bishops appointed by the Pope with this designation have dioceses in countries now possessed by non-Christians, especially in the East.

IN SPIRITUALIBUS (*Lat.*), in spiritual affairs, in opposition to *in temporalibus*, in temporal business. In speaking of the members of the upper house of the British Parliament, we use the phrase, the Lords spiritual and temporal, meaning the bishops and lay peers.

INSTITUTE of FRANCE (*l'Institut de France*), the collective name of the five Academies, which have their seat in a special building at Paris called the Palais de l'Institut. (1.) The French Academy, established in 1635 by Cardinal Richelieu, for the cultivation and advancement of the French language and literature. There are forty members (the Forty Immortals), who still hold sway over language and literature, although the great dictionary they undertook many years ago has made little progress. (2.) The Academy of Inscriptions and Belles Lettres, founded in 1701 for historical, archæological, and philological researches; also with forty members. (3.) The Academy of Sciences, founded by Colbert in 1666; there are eleven sections, with sixty-five members. (4.) The Academy of Fine Arts, founded by the painter Lebrun, in 1648, and remodelled by Colbert in 1664 as the Royal Academy of Painting and Sculpture, with forty members. These four Academies have undergone many changes of constitution and name (Royal, Imperial, National), and in 1803 a new branch was added, which in 1832 became (5.) the Academy of Moral and Political Sciences. The Academicians receive a pension of 1500 francs, and each Academy elects new members to fill vacancies in its body. Every new member of the French Academy is elected into a particular chair, and it is his duty on taking his seat to pronounce a formal harangue on the life and merits of his predecessor in that chair, to which a reply is made by another member.

INSTRUMENTATION, in Music, the artistical arrangement of a piece of music for the various instruments of an orchestra, with special reference to their several powers and peculiarities, and with the view of producing the intended effect. The written music is called the *score*.

INTENSITY OF SOUND. This is synonymous with loudness, and is proportional to the square of the aërial vibra tions in the case of sounds of the same pitch and character.

INTERMEZZO (*Ital.*), an interlude or short musical comedietta serving to fill up the time between two acts of the principal piece.

INTERNUNCIO (*Ital.*), a representative of the Vatican of lower grade than a nuncio at the court of a Roman Catholic sovereign.

INTERPELLATION (*Fr.*), a question addressed in a parliamentary assembly to some member of the Government, with the view of obtaining information as to some occurrence or proceeding. To interpellate is to ask for an explanation.

IRRATIONAL, in Arithmetic, a term applied to a number whose ratio to unity cannot be exactly expressed, an approximation only can be made, but this may be made continually closer. The numerical ratio of the circumference of a circle to the diameter is irrational. The roots of most whole numbers and logarithms are irrational. Such numbers are termed Surds. CIRCULATING DECIMALS are cases of this kind. In Algebra the term is applied to expressions involving fractional indices or radical signs.

IRRATIONALITY OF DISPERSION, in Optics, a term applied to the irregularity of the relative distances of the lines in the prismatic spectrum when prisms of different materials are employed. It arises from the different powers of dispersion possessed by different bodies.

IRVINGITES, a sect of Christians, followers of Edward Irving, who was born at Annan in Scotland in 1792 and died in 1834. They style themselves the Catholic Apostolic Church, believe in the revival of the spiritual gifts of the apostolic times, such as the power of speaking in unknown tongues, and expect an early appearance of the millennium. The church dignitaries are styled apostles, prophets, evangelists, and shepherds; the officers of the congregations are angels, elders, priests, and deacons. The services are conducted with much pomp. This sect has obtained converts among the upper classes in Germany.

ISOBARIC LINES or **ISOBARS** (*isos*, equal, *baros*, weight: *Gr.*), in Meteorology, are the lines drawn on the earth's surface to connect places where the barometer at a given date, or on the mean of the year, indicates the same atmospheric pressure.

ISOCLINAL LINES (*isos*, equal; *klinein*, to bend down: *Gr.*), in Terrestrial Magnetism, are lines which connect places on the earth's surface where the needle has the same inclination.

ISOGONAL LINES (*isos*, equal; *gonos*, an angle: *Gr.*), in Terrestrial Magnetism, are those which are drawn through places on the earth's surface where the declination of the needle is the same, because such lines make the same angle with the meridian.

IVORIES, ancient and mediæval carvings in ivory preserved in museums and much prized by antiquarians. They are usually in the form of statuettes, busts, crucifixes, diptychs, triptychs, and panels. There are many specimens in the British Museum, South Kensington Museum, and Liverpool Museum. The museums in Italy are also rich in these objects. *Fictile Ivories* are casts in a plastic material from the original pieces.

IVORY, VEGETABLE, is the white ivory-like albumen which envelops like a thick shell the kernel of the fruit produced by the *Phytelephas macrocarpa*, a palm growing in tropical South America. It is the Corozo Nut of commerce. This substance is worked up into buttons and numerous little ornamental articles. The nuts of a palm, *Sagus amicarum*, growing at the Friendly Islands, afford a nearly similar material.

J

JAGGERY, a coarse sugar, obtained in tropical countries from the juice of several palm trees.

JOSS HOUSES. Chinese temples are so termed by European travellers, who are said to have obtained the name by corrupting the Portuguese word *Deos*, God.

JUDICATURE, HIGH COURT OF. By an Act of Parliament passed in the session of 1873 (since amended and extended by other Acts), the Courts of Queen's Bench, Exchequer, and Common Pleas, the Court of Chancery, the Probate and Divorce Court, and the Court of Admiralty were abolished as separate courts, or rather were consolidated, and made to constitute the Supreme Court of Judicature. This court was made to consist of two divisions: the High Court of Justice and the Court of Appeal. The distinction between Law and Equity is no longer observed, but both branches of law are administered in the High Court of Justice. That court now consists of five divisions—namely, the Chancery division, the Queen's Bench division, the Common Pleas division, the Exchequer division, and the Probate, Divorce, and Admiralty division.

Appeals lie from the High Court of Justice to the Court of Appeal, and the ultimate court of appeal is the House of Lords The principal object of these revolutionary Acts was to break down the technical distinction between Law and Equity, which had prevailed for centuries, and to assimilate the procedure in all the courts Suitors may now obtain a complete remedy in the court to which they first apply, instead of being compelled to seek the enforcement of their 'legal rights' in one court and that of their 'equitable rights' in another when the same subject matter and the same persons are concerned The existing judges were retained, but they were empowered to dispense both law and equity in their courts, according to the circumstances of the cases brought before them Mere technical errors in procedure have not now the same fatal effect as formerly, being in most cases easily remediable Substantial justice, not the exact compliance with precedent, ought to be the main object in view in administering the law between party and party

JUNIUS, The Letters of, a series of letters on the politics of the time, which appeared in the 'Public Advertiser,' with the signature of 'Junius,' in the years 1769 1772 They attracted much attention on account of their bold and powerful attacks on the ministers, and of the excellent language in which their bitter invectives were expressed The government of the day prosecuted the printer, the law officers of the Crown declaring one of the letters to be 'a daring, scandalous, seditious, and dangerous libel' Every effort was employed to discover the author, but the secret has never yet been revealed. The conjectures on this head have been numerous, and several volumes have been written on the subject There seem to be fewer objections to the supposition that Sir Philip Francis, who had been employed in a government office and who died in 1818, was the author than to any other

K

KAIMACAN (a deputy *Arab*), the governor of a district in Turkey

KALMUCKS an Asiatic people of Mongolian race, living a nomadic life on the steppes and mountains of Turkestan, Mongolia, and Southern Siberia They number about 600 000 souls, are in part independent, and in part under the rule of the Russians and Chinese They are chiefly Buddhists, and their wealth consists of horses and cattle

KALO (formerly Taro), is the name given by the Polynesians to the *Colocasia esculenta*, nat order *Araceæ* [See Arum] It is extensively cultivated in wet places on account of its edible roots which are baked in an oven made in the ground, and are afterwards well beaten on a board with a stone pestle. It is then placed in a calabash and made into a paste with water, which is allowed to ferment for two or three days when it is considered fit to eat This paste is the *poi* of the Sandwich Islanders. *Paiai*, or hard food, is the name given to the pounded root before water has been added. In that state it is packed in leaves for carriage It is said that a piece of ground forty feet square planted with kalo will support an Islander for a whole year, and a square mile would suffice for 15,000 people for that space of time

KALPAK (*Turkish*) a hat made of lambskin amongst the Tartars, also the high caps made of felted hair worn by the Armenians, also a part of the Hungarian national costume

KAROSS, a cloak composed of the skins of animals neatly sewn together, and worn by the Caffre chiefs in South Africa

KEUPER, in Geology the German name of the uppermost division of the Trias system It is composed of a series of saliferous and gypseous shales and sandstones which reach a thickness of 1000 feet in South Germany, in which country it rests upon the Muschelkalk, another division of the Trias, which is wanting in England In this country the Keuper is less developed, but the 'bone bed of Devonshire and Gloucestershire, which abounds in the remains of saurians and fish, belongs to it

KIMMERIDGE CLAY, in Geology, the lower division of the Upper Oolite in England which takes its name from Kimmeridge, in Dorsetshire The beds consist chiefly of a bituminous shale several hundred feet thick, and forming here and there an impure coal. The shells are marine, and as the remains of plants are scanty, it is thought that the bitumen may be of animal origin

KINEMATICS (*kinema*, movement: *Gr*), a branch of Mathematics dealing with the motions, whether simple or compound, of particles and bodies, introducing the conceptions of time and velocity, but excluding that of force.

KISTVAEN (*kist*, a chest: *Ang. Sax.*; *maen*, a stone: *Brit.*), an ancient sepulchral structure, composed of three or four upright stones, arranged so as to form a small chamber, with a large flat stone across the top. After the body had been placed therein, it was covered with a mound of loose stones and earth forming a tumulus.

KNIGHT'S PROBLEM at Chess; this consists of placing a knight upon any one of the sixty-four squares of a clear chess board, and making him leap successively into every other square without entering any one a second time.

KOLA NUTS, the seed of a tree, *Sterculia acuminata*; nat. order *Sterculiaceæ*, growing in tropical Africa. They are about the size of a pigeon's egg and of a brown colour, with a bitter taste. The natives prize them highly, and are in the habit of eating part of one before taking a meal, in order to improve the flavour of anything they eat or drink afterwards. Analysis shows that they contain theine.

KRUMEN or **KROOMEN**, the black inhabitants of a part of the west coast of Africa, south of Liberia, called the Kru Coast. They are intelligent and muscular, and are much sought after by merchant vessels and men-of-war to perform the rougher duties of the service.

L

LACQUER, JAPAN. The material for this varnish is obtained by making incisions in the bark of a tree (*Rhus vernicifera*, nat. order *Terebinthaceæ*) when the sap is rising. Lacquered articles in the form of cups, dishes, &c., are universally employed by the Japanese, instead of crockery and glass. Good old lacquer-work is very costly even in Japan; the best is usually in the form of small boxes. The tests of good lacquer are said to be its high finish, its satiny, oily feel, and its resistance to the pressure of the thumb nail.

LACTIN (*lac*, milk: *Lat.*), is the sugar of milk, and is obtained by evaporating whey to a sirupy state, and allowing the lactin to crystallise out. When purified it forms white four-sided prisms of a sweetish taste. It is composed of carbon, hydrogen, and oxygen, twenty four atoms of each.

LADY CHAPEL, a chapel in churches dedicated to the Virgin. In English cathedrals it is usually placed at the extreme east end beyond the chancel.

LANCEWOOD, employed by coachmakers on account of its toughness and flexibility, is procured from a South American tree, the *Duguetia Quitarensis* of botanists, nat. order *Anonaceæ*, to which order the CUSTARD APPLES belong.

LAPITHÆ. [See CENTAUR, p. 123.]

LASSO (*Span.*), a strip of hide many yards in length with a noose at one end, employed by the GAUCHOS of South America in capturing wild cattle, horses, and sheep. When the man is on horseback, it is skilfully thrown in such a manner that the noose catches the neck, horns, or legs of the animal.——The Bolas, used for the same purpose, are two metal balls attached to the ends of a thong, itself attached to the end of a long strip of hide. When chasing an animal, the man keeps the balls whirling wide apart over his head, until the proper moment arrives for launching them. On striking the object they twist round it and effectually secure it.

LATTICE LEAF PLANT, a water plant, the *Ouvirandra fenestralis*, nat. order *Naiadaceæ*, growing in Madagascar. The leaf is very remarkable from being pierced with holes like a coarse sieve, the cellular tissue not filling up the meshes of the vascular tissue. There are two other species of the genus in Madagascar, but only one of these has skeleton leaves. A fourth species has been lately found in Eastern Africa.

LAUGHING GAS. [See NITROUS OXIDE, p. 494.]

LECTERN, or **LETTERN** (*lectare*, to read: *Lat.*), the desk or stand on which the large books used in the services of the Roman Catholic churches are often placed. They are frequently seen as ornamental objects in modern churches.

LEONIDES, the name of the meteor showers, which occur annually from the 12th to the 14th of November. Their radiant point is the star ε, in the Leo constellation.

LETTERS OF THE ALPHABET, THE, are usually divided into vowels and consonants. The sounds of the latter are classified by phonologists, according to the organs used in pronouncing them, into (1.) Gutturals (absent in English, but heard in *ch*, of the Scotch *loch*, and the German *ach*) from *guttur*, the throat: *Lat.*, because the back of the mouth at the top of the throat is brought into play; (2.) Palatals—hard C and G, K, Q; (3.) Nasals (M, N), from *nasus*, the nose: *Lat.*; (4.) Linguals (D, L, T), from *lingua*, the tongue: *Lat.*; (5.) Labials (B, F, P, Ph, V), from *labia*, lips: *Lat.* As to the remaining letters of the English language, H is an aspirate, and S and Z are sibilants (*sibilare*, to hiss: *Lat*). R is a compound lingual and palatal, X a compound palatal and sibilant. Another division of letters according to their sounds is into—(1) Tenues—K, P, T; (2) Aspirates—H, Th, Ph, F, V, and the German Ch, (3) Half vowels—R, L; (4) Sibilants—S, Sh, Z; (5) Nasals—M, N; (6) Medials—G, D, B In English forty-two elementary sounds are represented by twenty-six letters Eighteen of the elementary sounds are vocalic. 'When we come to compare,' says Dr Angus, 'the two and forty sounds of our language, with the six and twenty letters that are employed to represent them, we see at once the deficiencies of our alphabet The theory of a perfect alphabet requires that every simple sound should have a single sign, that no sound should have more than one sign, and that similar sounds should be represented by similar signs, these last varying according to the degrees of likeness which the sounds represent. If the English alphabet be tested by these three principles, it will be found singularly unsatisfactory It is at once uncertain, inconsistent, erroneous deficient, and redundant'

LINGULA (a little tongue: *Lat*), a genus of bivalve mollusks belonging to the class of Brachiopoda, and remarkable for its immense duration in geological time, having been found in the oldest conchiferous rocks (Cambrian epoch), and being still represented by living species

LONGEVITY (*longævitas*, long life *Lat*) Flourens, the French physiologist, was of opinion that the natural duration of the life of an animal is five times the period it takes to arrive at maturity Applying this to the human race, it would appear that the natural expectation of life is at least one hundred years. Dr P Hood, in writing upon this subject, says, that 'most, if not all, of our illnesses are the result of one of two things, either of our ignorance or of our indiscretion—our ignorance in not being acquainted with the laws that govern health, or our indiscretion when we know them, in failing to yield obedience to them Nothing can be easier than to test the truthfulness of this painful aphorism, if those who hear it will apply it to the cases of the persons with whom they have been intimate, and who have died long before their time. They will usually discover that some imprudence had been committed by the individual, either for a longer or a shorter time, he may have indulged too freely in the pleasures of the table, abandoning the exercise which was formerly customary to him; he may have become a daily or nightly spirit drinker—one of the most undermining habits that can be pursued, even although it may not appear to produce any ill effects at the time. He may, in fact, have transgressed the majority of those laws which govern our health, in some instances knowingly, in others unconsciously, the result however being always the same. Excess in eating, in drinking, in fasting, in smoking, may all prove factors in the shortening of the duration of life, as well as undue exposure to cold with an insufficient amount of clothing; but, perhaps, the most fertile source of all is neglect of the signs of coming diseases with which Nature invariably furnishes us. If we allow these signs to pass by, or to escape us, without attempts at correcting what they indicate, a downward progress is suffered to continue, which might otherwise have been long retarded' How desirable is it, then, that instruction in regard to the leading rules for the preservation of health, and to the scientific truths on which they are founded, should be communicated to us in our early years along with—one might almost venture to say before—the mysteries of Latin composition and Greek verse. Since this subject has an immediate bearing upon our corporeal well being, and therefore on our happiness throughout our lives, it surely ought to stand amongst the foremost branches of our education. But what is the fact? The great majority of children are taught nothing whatever upon this head, and they grow up in lamentable ignorance of the elements of the great science of living The calamitous consequences of this neglect are only too plain. By the non-observance of a few simple rules, a vast number of persons born into the world are cut off prematurely, besides having their shortened lives afflicted with various avoidable diseases. (On this subject a series of little works entitled 'Health Primers,' published by D Bogue, or another series, 'Manuals of Health,' S P.C.K, may be profitably consulted.)

M

MÆNADS, or **MÆNADES**, the Bacchantes, or followers of Dyonysos or Bacchus, who derived their name from their frantic behaviour (*mainomai*, to rage: *Gr.*).

MAFIA, a secret society in Sicily, with the same objects as the **CAMORRA** (*St*) at Naples.

MAGYAR, one of the Ugrio-Finnic tongues, spoken by the people of Hungary.

MAHABHARATA in Sanscrit Literature one of the two great national epics, consisting of nineteen divisions with 220 000 lines The principal subject is the contest of the Bharata (Pandu and Kuru) for the throne of Hastinapura but a great number of other Indian stories are interwoven The work has been printed in four volumes, and translations have been made into French and German

MAHADEVA one of the titles of the Hindoo deity Siva

MAHRATTI the language spoken by about 15½ millions of persons living in the states into which the former Mahratta empire has been divided Gwalior Indore Baroda, &c It is derived from the Sanscrit

MAJOS (*Span*) the male inhabitants of some valleys in Andalusia noted for their gay costume and blustering behaviour The women who are worthy companions of their mates are termed *Majas*

MAJUSCULE, in Palæography a writing in which the letters are all capitals employed in ancient manuscripts

MALAGASY the language spoken in Madagascar it is a dialect of the widely spread Malayo Polynesian tongue of which it is the most westerly member Many African words are intermixed

MALAY LANGUAGES a distinct family of tongues spoken in the Philippine Islands, the islands of Formosa Borneo, Celebes, Sumatra, Java, and the Malay peninsula. When the Malays were converted to Mohammedanism they adopted the Arabic *characters*, in which all their literature is written and their correspondence has been conducted with them from that time to the present although said to be unsuited to the Malay tongue To this family belong the Malayo-Polynesian languages spoken by the Polynesian islanders. There are two branches one spoken by the dark race inhabiting Fiji and other islands north-east of Australia the other by the brown race dwelling in New Zealand the Samoan Islands, the Marquesas Tahiti and the Sandwich Islands This tongue is highly vocalic soft, and musical

MALMSEY a wine said to derive its name from Malvasia in Greece, or Crete During the Middle Ages it was highly esteemed In that old poem the 'Morte d Arthure' we read of malvesye and muskaddel those mervelyous drinkes' The most celebrated wine of this name in later times is that made from a peculiar grape in the island of Madeira, a strong luscious wine with powerful bouquet

MALPIGHIAN CORPUSCLES minute round bodies, found in the spleen and kidneys. They were named after Malpighi an Italian anatomist of the seventeenth century

MAN, RACES OF Many attempts have been made to mark out the races of man by clear, well defined lines of separation, but ethnologists are at variance as to the number of divisions and as to the characters upon which the varieties are to be limited and circumscribed There are classifications of races (says Professor Owen) varying from thirty to the three predominant ones which Blumenbach first clearly pointed out—the (black) Ethiopian the (brown) Mongolian and the (white) Caucasian or Indo European These varieties merge into one another by easy gradations The Malay and the Polynesian link the Mongolian and Indian varieties and the Indian is linked by the Esquimaux again to the Mongolian The inhabitants of the Andaman Islands New Guinea, New Caledonia and Australia in a minor degree seem to fill up the hiatus between the Malay and the Ethiopian varieties and in no case can a well marked, definite line be drawn between the physical characteristics of allied varieties these merging more or less gradationally the one into the other

The following arrangement of the principal races is perhaps as convenient as any that have been sketched —

WHITE RACES

1 *Arabian* Nose prominent lips thin, beard abundant hair straight or flowing

2 *Abyssinian* Complexion scarcely becoming florid nose prominent, hair crisped

BROWN RACES

3 *Mongolian* Beardless hair quite straight and very long (including the American Indians)

4 *Hottentot* Negro features, close woolly hair, diminutive stature

5 *Malay* —Features not prominent in the profile, complexion darker than in the two preceding races hair straight or flowing (including the Malayo Polynesians New Zealanders Australians the people of Madagascar, and the Californian Indians) See POLYNESIA

BLACKISH BROWN RACES

6 *Papuan* Features not prominent in the profile, beard abundant, skin harsh to the touch, hair crisped or frizzled

7 *Negrillo* —Beardless, stature diminutive features approaching those of the negro, and the hair woolly

8 *Indian* —Features approaching those of the Arabian, hair straight or flowing

9 *Ethiopian* —Complexion and features intermediate between those of the Indian and Negro, hair crisped

BLACK RACES

10 *Australian* —Negro features, with straight or flowing hair

11 *Negro* —Close woolly hair, nose much flattened, and lips thick

MANX, that dialect of Celtic spoken in the Isle of Man. It is rapidly becoming extinct

MAORIS, the native name of the New Zealanders, a branch of the brown Malayo Polynesian race. Their traditions say that their ancestors came from the north and north-east They are a fine race of men, physically

MARCIONITES, a religious sect which arose in the second century, so called from their founder, Marcion, who seems to have been imbued with Gnostic ideas They imagined that besides the two principles of good and evil there was a third the creator of the world and the God of the Jews who was partly good and partly evil It was the good principle that sent Jesus Christ into the world that the evil principle might be extirpated and the Jewish Deity neutralised

MARK the new silver coin of the German empire its value is about 11¾d It is divided into 100 pfennigs

MARS Professor Asaph Hall of Washington, by employing a refractor of 26 in aperture, has discovered that this planet has two small moons circling round him at the distances of about 12 400 and 3700 miles from his surface, and in periods of about 30h 17m, and 7h and 39m respectively The motion of the latter round its primary is effected in less than one third of the time of the primary's rotation, a case unique in the solar system These moons which have been named Deimos and Phobos have diameters of six or seven miles. The mass of Mars is now believed to be about the 1200th part of the earth's mass, or the 3 093 500th part of the sun's mass

MARSEILLAISE the song written by Rouget de Lisle, at Strasburg in 1792 beginning, Allons enfans de la patrie and set to a German melody It became a favourite song of the revolutionary party

MATADOR (the killer *Span*), the man whose duty it is at a bull fight to kill the bull after it has been sufficiently tormented by others

MATE, YERBA DE or Paraguay Tea, is the leaf of the *Ilex Paraguayensis* a small tree, allied to our holly growing wild in the forests of Brazil and the Argentine Republic. The leaf is prepared for use by roasting Its infusion forms a favourite beverage with the people of South America in place of ordinary tea and coffee It contains like them the principle theine The usual mode of taking it is to suck it from the cup through a tube

MATICO (*Span*), the leaves of *Piper angustifolium*, nat order *Piperaceæ*, a native of South America. An infusion is employed as a styptic in internal hemorrhages and in affections of the mucous membrane.

MAUND, a standard weight of British India, equal to 100 lbs. English Troy weight It is divided into forty seers

MAZER, a wooden cup or bowl, often carved or otherwise ornamented, and deriving its name from being usually made of mazer or maple wood (*Maderholz Germ* speckled wood *i e*, maple)

MEASURES [See WEIGHTS AND MEASURES (Sup)]

MEGALESIAN GAMES, ancient Roman games instituted in honour of Cybele the great (*megale Gr*), goddess

MEGALITHIC REMAINS (*megas*, great, *lithos* a stone *Gr*) prehistoric arrangements of large blocks of stone usually in circles or avenues Stonehenge is the finest example in Britain Their origin and purpose have been the subject of much discussion Formerly those in this country were attributed to the Druids Some have thought them to be places for religious worship others places of judicial meeting or places of sepulture for chiefs or warriors, and even an astronomical purpose has been suggested

MELANESIA (*melas* black, *nesos*, an island *Gr*) a name given to those islands in the South Pacific which lie between the meridians of the Tonga Islands and New Guinea, and which are inhabited by black races distinct from the brown Polynesians [See PAPUANS, NEGRITO (Sup)]

MELAPHYRE (*melas* black *phurein*, to mix together *Gr*) a volcanic rock having a base of black augite with disseminated crystals of felspar It is a variety of black porphyry The term has been loosely applied to a number of Palaeozoic eruptive rocks differing widely in mineralogical composition

MERCAPTAN, in Chemistry, an alcohol in which the oxygen of common (ethylic) alcohol is replaced by sulphur It is a whitish fluid lighter than water with an extremely penetrating and offensive odour so much so that until largely diluted with common alcohol it can hardly be approached

MERIDIAN CIRCLE the same as a Transit Instrument, which see

MESTIZO (*Span*), in America the child of a white person and an Indian, whilst the name Castizo is given to the child of a white person and a Mestizo.

METAMERIC, a term applied by chemists to bodies which have the same chemical composition and atomic weight, but differ in some of their properties

METAMERISM (*meta*, together *meros*, a part *Gr*), in Zoology, the property in an animal of being constructed by a repetition of like parts (*metamera*); as in worms, where ring succeeds ring

METAYER SYSTEM of land tenure. This consists of the payment of rent by the tenant, not in money, but by a share of the produce of the land, usually one half (*medietas*, a half: *Lat.*). The arrangements between landlord and tenant vary in different places as to their respective contributions to the required materials, seeds, manure, and implements.

METEOROLOGY. 'It cannot be disputed,' said Sir John Leslie many years ago, 'that all the changes which happen in the mass of our atmosphere, involved, capricious, and irregular as they may appear, are yet the necessary results of principles as fixed, and perhaps as simple, as those which direct the revolution of the solar system.' The rotation of the earth on its axis is the chief cause of changes in the weather, and the sun must be looked upon as the *primum mobile* of meteorological phenomena. The main object of meteorologists in all their investigations is the establishment of data by which the state of the weather at a future time may be foretold. Although a scientific basis for this has not yet been laid, yet through the combination of observations and the use of the electric telegraph, a beginning has been made, and in many cases prognostications for a short date have proved to be fairly accurate. The Government has established a Meteorological Office in London, which issues daily to subscribers, and for exhibition at various public offices, seaports, and fishing stations, a weather chart giving a graphic representation of (1.) the barometrical pressure, (2.) the temperature, (3.) the wind and sea disturbance, and (4.) the weather and state of the sky over the United Kingdom and some of the adjacent parts of the Continent, for 8 A.M. every morning. Besides this, the same Office regularly publishes in some of the daily newspapers little charts of the weather founded upon the same returns which afford materials for the construction of the larger chart. These smaller charts exhibit (1.) the isobars of our islands, that is, the lines of equal barometrical pressure, (2.) the direction and strength of the wind in different places, (3.) the state of the weather and sky at different localities, and (4.) the state of the sea in different parts. Moreover, whenever the Office receives telegraphic reports indicating that a considerable disturbance of the atmosphere has reached or is near our shores, warnings are sent by telegram to those parts of the coast which are apparently threatened. Telegrams are now regularly sent from America to our Meteorological Office when a storm threatens to cross the Atlantic, and the information is at once forwarded to the principal ports. Such warnings are valuable; at the same time experience shows that whilst some storms are turned aside on crossing the ocean and never reach us, others arrive unannounced.

Some meteorologists are of opinion that the seasons run in cycles of about eleven years, and that a period of heat and drought, usually of three years' duration, is experienced as part of a cycle. The cycle, however, appears to be somewhat irregular, being sometimes advanced and sometimes postponed for a year. Again, it has been thought that there is a correspondence between the dry seasons and the minima of sun spots and between the wet seasons and the maxima of sun spots, but this hypothesis does not seem to have been satisfactorily made out at present.

Rain.—The greatest known deposit of rain on the globe takes place at Cherra Ponjee, in the Khasyah Mountains, 300 miles north-east of Calcutta, at which spot there is an annual fall of 610 inches, and nearly as much falls at Dhurmsala, in Western India. In Britain, the heaviest deposit is at Seathwaite, amongst the Borrowdale hills in Cumberland, where there is an annual fall of 165 inches.

The experiments of Dr. Tyndall have shown that the minute quantity of water which is suspended as invisible vapour in the atmosphere acts to an astonishing degree as a warm clothing to the earth. Although the atmosphere usually contains only one particle of aqueous vapour to 200 of air, yet that single particle absorbs 80 times as much heat as the 200 particles of air. If the aqueous vapour were removed from the air overspreading this country for a single summer night, every plant not capable of bearing extreme cold would be destroyed. The radiation of heat from the ground would be so great that intense frost would prevail long before morning.

Water being heavier than air, the suspension in the atmosphere of clouds and visible vapours is an unexplained fact. The vesicular condition of the particles has never been proved, and if it had been, would not throw light upon the matter.

Wind.—When the air has a motion of from 30 to 35 miles per hour, the wind is considered high, and if the rate of motion were 50 miles per hour, there would be a storm, and the pressure exerted by the wind would be about 12 lbs. on the square foot. But on the 27th of December 1868, the anemometer at the Bidston Observatory, Birkenhead, registered a velocity for a single hour of 92 miles, and the pressure instrument registered pressures exceeding 70 lbs. on the square foot.

Observatories at Elevated Stations.—As it is manifestly desirable to ascertain whether observations taken in elevated positions may not throw light upon the constitution of the atmosphere and the laws determining its changes, many observatories have been lately established at points raised a considerable height above the sea. In France there is a meteorological station on the Puy du Dome (Auvergne) at the height of 4809 feet, and another has been placed on the Pic du Midi (Pyrenees) at 9439 feet above the sea. A third is about to be built, at the height of 6200 feet, on Mont Ventoux, an isolated peak near Avignon. In Upper Austria there is a station on the Schafberg, nearly 6000 feet above the sea. Three stations in Italy have been formed at the heights of 8360, 8343, and 7087 feet above the sea. In Sicily, upon Mount Etna, a station is to be formed at the height of 9652 feet. At the hospice of St Bernard there is a station 8130 feet above the sea. There are stations in the United States on Mount Washington, Mount Mitchell, and Pike's Peak, Colorado, which have the heights of 6600 feet, 6691 feet, and 14,216 feet. The only station in Great Britain above 3000 feet is that about to be built on Ben Nevis.

MICRONESIA (*micros*, small; *nesos*, an island: *Gr.*), the name given to the small chains, or clusters of islands scattered over that part of the Pacific, lying to the W. and S.W. of the Sandwich Islands, and to the N. of the equator. The Caroline Islands, Marshall Islands, and the Ladrone Islands form part of Micronesia. They are inhabited by Malayan races.

MIKADO, the title of the Emperor of Japan. Formerly the Mikado was only the spiritual head of the State. The temporal sovereignty was exercised by the Tycoon (Shogun or Siogun), who commanded the army, received the revenues, and governed the country; whilst the Mikado, remaining secluded within his palace, was honoured as a deity. In 1867, however, it was discovered that he was man the Tycoonate was abolished, and the Mikado alone now governs Japan with the assistance of a body of ministers. [See DAIMIOS (*St.*).]

MILDEW, the name of various minute fungi, which in the form of a fine powder attack growing plants, especially in damp seasons. They appropriate the juices of the plants upon which they settle, and produce disease. Mycologists assign them to several genera. The vine mildew, *Erysiphe* or *Oidium Tuckeri*, has done immense damage of late years in the vineyards of Europe. Its ravages, however, can be kept in check by the application of sulphur. The black or sooty mildew has attacked the orange and coffee plantations of various parts of the world, and it frequently appears in our conservatories. The only remedy for this plague seems to be careful washing and syringing; but these operations cannot be carried out where plantations are concerned. The wheat mildew, *Puccinea graminis*, is also a plague for which no remedy has been discovered. One form of rust is an early state of this mildew.

MINEVERE, a fur mentioned in old English writers, and by the heralds. It is said to have been taken from the white belly of the grey squirrel; but some contend that it was the fur of the ermine spotted with the fur of the weasel.

MINK, the *Putorius Lutreola* of naturalists, an animal of the Weasel tribe which affords a valuable fur, and is a native of Canada and the Columbia district of North America.

MINORITES (*fratres minores*: *Lat.*), one of the names given to the FRANCISCAN Friars, who were also called Barefooted and Grey Friars.

MINORITIES, REPRESENTATION OF. This does not mean that all minorities of voters ought to be represented; but only such minorities as are large. Mr. J. S. Mill contended that 'a mode of voting which does not keep this object in view is contrary to popular government; it does not sum up the opinion of the community correctly. There is no true popular representation if three-fifths of the people return the whole House of Commons, and the remaining two-fifths have no representatives. Not only is this not government by the people, it is not even government by a majority of the people, since the government will be practically in the hands of a majority of the majority. If numbers are to be the rule, a third of the people ought not indeed to have two-thirds of the representation, but every third of the people is entitled to a third of the representation.' To carry the representation of minorities into effect, it has been proposed that every constituency should have three members, whilst each elector should only be allowed two votes; or else that having as many votes as there are members to be elected, he should be allowed to accumulate his votes on one candidate. By either of these plans a minority amounting to a third of the constituency, may by acting in concert, and determining to aim at no more, return one of the members.

MINUSCULE (*minusculus*, rather small: *Lat.*), the style of writing in old manuscripts where small (not capital) letters were employed; used in opposition to MAJUSCULE (*St.*).

MISERERE (have mercy: *Lat.*), a name given to a bracket on the underside of the seat of a canon's stall in an old church. Such seats were made to turn up on a hinge, and the underside was frequently richly carved.

MITRAILLEUSE (*mitraille*, grape shot: *Fr.*), a gun with a number of barrels firmly united together, which can be rapidly loaded and discharged. The French mitrailleuse has twenty-five barrels, the Austrian thirty-seven. The GATLING GUN (*St.*) is a species of mitrailleuse. These guns are mounted on carriages like cannons.

MOCASSIN (*Indian*) a shoe made of skin worn by the Indians of North America

MODIUS (a corn measure: *Lat*), an object shaped something like a gardener's flower-pot, often seen on the head of Jupiter Serapis in Roman sculpture.

MŒSO-GOTHIC an ancient Low-German dialect allied to modern English through the Anglo Saxon. The only remains of it consist of portions of the Scriptures translated by Bishop Ulphilus, about the year 360 for the use of the Visigoths, who had a settlement in Mœsia near Mount Hæmus

MONERA (*moneres*, single: *Gr*), the name given by Professor Haeckel to a group of animal forms, the most rudimentary known, including AMŒBA (*St*) and others

MONGOLS, a people forming the principal part of the inhabitants of Mongolia, one of the great provinces of the Chinese Empire. They profess Buddhism, and their tongue is one of the ALTAIC (*St*) languages. They were formerly predatory marauders, but now support themselves by rearing camels horses, and cattle, and by the chase. They are divisible into three main branches the East Mongols living east and west of the Gobi Desert, the West Mongols or KALMUCKS (*St*), and the Burats who live in the Siberian government of Irkutsk

MONISM (*monos*, single: *Gr*), the doctrine of unity, or that of a single principle of being in opposition to Dualism The monistic philosopher holds that there is no force without matter and no matter without force

MONOCHLAMYDEOUS (*monos*, single, *chlamys*, a garment: *Gr*), in Botany, a term applied to flowers which have only one floral envelope, whilst the Dichlamydeous flowers have both calyx and corolla.

MONSTRANCE (*monstrare*, to show: *Lat*), the vessel in which the consecrated wafer is placed when it is held up before the congregation in the Mass

MOON. [See p 470] During its year of 345¾ of our days there are only 11¾ lunar days, each lasting 29½ of ours. The range of temperature on the surface of the moon between the lunar midday and midnight is very great, perhaps as much as 500° F The area of the moon is about 14,600,000 square miles. Her surface has been very carefully examined, mapped, and photographed. Besides the mountain ranges and cones, with deep craters, that diversify her face, there are bright radiating lines of immense extent, the meaning of which is not comprehended. One of these lines can be traced nearly from one side to the other of the hemisphere exposed to our view. Some of the numerous craters are much larger than the largest craters on the earth, being more than 100 miles in diameter, with walls upwards of 10 000 feet high, but there are also many very small craters

MULCHING, a gardener's term for the operation of spreading some material like spent manure, leaf mould, or short grass mown from a lawn, upon the ground around plants, with the object of preventing too rapid evaporation from the soil during dry weather.

MURÆNA (an eel: *Lat*), in Ichthyology, a genus of marine eels, to which belongs the *M. Helena*, a Mediterranean fish prettily marbled with brown and yellow, much esteemed by the ancient Romans, who kept it in tanks in readiness for their banquets, and produced it alive in water on the table that the guests might admire its motions and colours before it was cooked One wealthy tyrant was in the habit of flinging slaves who had offended him alive into his fish ponds as food for his murænæ

MUREXIDE (*murex*, a purple dye: *Lat*), a body prepared from uric acid, which crystallises in small square prisms, having the property of exhibiting by reflected light a beautiful green metallic lustre, whilst by transmitted light they are deep purple red. They form pretty objects under the microscope. They are a compound of carbon, hydrogen, nitrogen and oxygen

MUSCOLOGY (*muscus*, moss: *Lat*), that division of cryptogamic botany which relates to the MOSSES and HEPATICÆ (*St*)

MYCELIUM (*mukes*, fungus: *Gr*), in Botany, the spawn or first product of the spores of fungi It is usually composed of minute threads, but it may have a membranous, a tubercular, or a pulpy structure. From it springs those varied forms which are known as mushrooms, moulds, &c, the subject of the study of mycologists

MYCOLOGY (*mukes*, a mushroom: *Gr*), the division of cryptogamic botany, embracing the fungi, under which are classed mushrooms, toadstools, green moulds, blights like the destructive oidium, and similar growths.

N

NARTHEX, a division in early Christian churches to which penitents and catechumens were limited, where night watches were held, and where corpses were placed during the funeral service. The narthex is still to be distinguished in a few old churches in Italy.

NATURAL SELECTION, Mr Darwin's expression for the process by which he believes that the various existing species of animals and vegetables have been evolved, viz., in consequence of certain forms or varieties possessing advantages over others in the struggle for existence. They may be considered as selected by nature to survive and perpetuate their kind, whilst the forms less advantageously endowed perish.

NATURE, LAWS OF, all the uniformities which man has discovered to exist among natural phenomena when reduced to their simplest expression. They are our statements as to the orderly sequence which we discern in the phenomena of the universe. It has been pointed out that these so-called 'laws' are of two kinds; one set being mere generalisations of phenomena such as the laws of planetary motion and the laws of chemical combination. These laws do not explain or account for everything. The other set of laws express the conditions of action of a force, the existence of which is made known to us by the direct evidence of our own consciousness. Laws of this kind are based on the fundamental conception of a force or power. If the existence of a force such, for example, as that of gravity is admitted, and the conditions of its action can be accurately stated, then the 'law' that expresses them may be said to govern the phenomenon, and any phenomenon which can be brought under that law is said to be explained. When any new phenomenon is explained it must be shown to be like something previously known, and thereby brought into conformity with some law.

NEBULÆ. [See p. 488.] It would appear from observations made at the Melbourne Observatory, Australia, that some of the nebulæ figured by Sir John Herschel at the Cape of Good Hope, have considerably changed their appearance, whilst others are so greatly altered as to be only recognised by their position. Two nebulæ have entirely disappeared. A few years ago all nebulæ which were irresolvable by the most powerful telescopes were deemed to be composed of matter in a state of vapour, but recent spectroscopic researches appear to show that only about one out of four of the irresolvable nebulæ is truly gaseous, as the rest give a faint continuous spectrum, thus proving that they are clusters of closely approximated stars which could be seen as distinct bodies if a sufficiently powerful telescope could be brought to bear on them. The true gaseous nebulæ do not afford a continuous spectrum, but one of three lines, two of which pertain to hydrogen and nitrogen, whilst the third has not yet been recognised.

NEGRILLO or **NEGRITO** (*Span.*), a blackish-brown race of men, inhabiting the New Hebrides, and some other islands of the South Pacific. They are small in stature, have the lower part of the face projecting, with the features and complexion of the Negro, and rarely a beard. The hair is more woolly than the Papuan's, but not so matted as the Negro's.

NEITH, a female deity in Egyptian Mythology, who was said to claim self-generation, 'I came from myself.' She was especially worshipped at Sais in the Delta, and was represented as a woman bearing a shuttle on her head; and sometimes by a vulture bearing on its head the Pharaonic crown.

NEOLITHIC. [See STONE AGE (*St.*).]

NITRO-GLYCERINE, a light-coloured oily liquid about 50 per cent heavier than water, prepared by causing a mixture of nitric and sulphuric acids to act upon glycerine. When pure it freezes at about 40° F., and in this state it is much safer to carry than when liquid. Its explosive power is estimated at from nine to ten times that of gunpowder. It is the basis of various explosive powders. [See DYNAMITE (*St.*).]

NORNS, the three sister fates of Scandinavia, who spin and weave the thread of human destiny, Urdhr, Verdhandi, and Skuld.

NORTH-EAST PASSAGE, the passage by sea from the North Atlantic Ocean, along the coast of Siberia, to Behring's Straits at the northern extremity of the Pacific Ocean. The North-East Passage has been recently made for the first time by a Swedish expedition, under Professor Nordenskjold.

NORWEGIUM (*Norvegia*, Norway), a metal detected in 1879, by Dr. T. Dahll, in a metallic compound of arsenic and nickel, from a mine in Norway. It is white with a faint shade of brown, is slightly malleable and fusible at a dull red heat. Its hardness is about that of copper. Density, 9·44; chemical equivalent, 145.

NOTOCHORD (*notos*, birth; *chorde*, a string: *Gr.*), or *Chorda dorsalis* (*Lat.*), a thread of cellular structure covered by a sheath running through nearly the entire length of the embryo of all vertebrate animals. It has been found also in the larvæ of some invertebrate Ascidiæ. Except amongst the lower vertebrates where no vertebral bodies are developed, the vertebræ, as the embryo grows, are deposited round the notochord, which thus forms the middle of the vertebral column.

NOUMENON, *pl.* NOUMENA (*Gr.*), in Transcendental Metaphysics, things *per se*, as distinct from their phenomena or appearances with which alone we are acquainted. It is admitted that noumena cannot be known by man, but it is asserted that it is necessary to postulate their existence.

NUDIBRANCHIATA (*nudus*, naked; *branchiæ*, gills: *Lat.*), an order of marine mollusks, usually of a snail-like form. Their branchiæ are exposed on the back or at the sides of the body, without the protection of a shell. There are numerous genera (Doris, Eolis, &c.) and species, many of which are very prettily coloured. They are found on all coasts, some being animal, others vegetable feeders.

NURAGHI, ancient round towers of stone, with internal chambers, found in Sardinia, and similar to the Irish round towers. They are of unknown date.

O

OBELISK. [See p. 503.] Pliny says that they were considered by the Egyptians to be symbolic of the solar rays. They were erected in pairs before the entrances to the temples. It is singular that they have only been found on the east bank of the Nile. Forty-two ancient obelisks are known, of which six are still erect in Egypt, and eleven are prostrate there, twelve are at Rome (but two of these are thought to be Roman work), two at Florence, one at Paris, and three at London (there being two small ones in the British Museum, besides the one brought from Alexandria in 1878, and erected on the Thames Embankment, which last bears the name of Thothmes III., by whom it was erected at Heliopolis, about 1500 B.C.). Finally, one was removed to the United States of America in 1879.

OBVERSE (*obversus*, turned towards: *Lat.*), in Numismatics, that side of a coin upon which the principal figure is stamped, the other side being the reverse.

OCEAN. [See p. 505.] The numerous elaborate investigations which have been made of late years by various special expeditions fitted out at the expense of different governments, especially the British, have thrown much light upon the secrets of the ocean depths, and many facts have been established which were not only new but quite opposed to previous beliefs. It was imagined, for instance, that animal life would entirely cease at a depth of 300 fathoms, but zoophytes, echinoderms, mollusks, annelids, and crustaceans of perfect organisation, as well as sponges and foraminifera, have been brought up from enormous depths. Indeed, animal life has been found at all depths to which the sounding line has reached. Again, it was previously thought that the temperature of the deep sea was everywhere 39° F.; but the temperature of the bottom of the ocean has been found to vary from 32° F. to 47° F., and that at points only eight or ten miles distant. The usual arrangement of the zones of temperature is that at the depth of about 500 fathoms there is a band with a temperature of 40° F. Above this, the temperature varies over different areas; that is to say, within the tropics the temperature of the upper water rises to the surface, whilst within the Arctic and Antarctic circles it falls. Beneath the neutral band, the temperature almost invariably sinks with increasing slowness until the minimum is reached at the bottom. This minimum varies in different localities; thus in the North Pacific the bottom temperature was always about 35° F., but near Tongataboo, within the tropics, in the South Pacific, the bottom temperature was 32° 9′ F. Over three-fourths of the Atlantic there is a nearly uniform bottom temperature of 35° 3′, but in the remaining fourth—namely, from the coast of South America to a line drawn from Tristan d'Acunha to Ascension and from the equator southward—the bottom temperature varies from 31° to 33° 5′. Thus the coldest water is spread over the bottom of the western portion of the South Atlantic. Whenever deep basins are shut in by submarine ridges which cut off the access of cold water from the open ocean, it is found that they are filled with comparatively warm water. This is the case in the Gulf of Mexico, and in the basins of the Banda, Celebes, and Sulu Seas. The evidence now obtained seems to show that the great ocean basins now existing have always existed, and that the present areas of land occupy the regions in or near which land has always been. The former were areas of subsidence from very early times, whilst the latter have been regions which were elevated under the strain of terrestrial contraction. The configuration of the bed of the ocean has been hitherto unknown, but its general features are now mapped. It appears that an elevated sinuous ridge starting from Greenland runs through the Atlantic from north to south at a mean depth below the surface of 1904 fathoms. Upon this ridge in the North Atlantic are the submarine 'Dolphin Rise' and the Azores. In the trough between this ridge and the west coast of North Africa rise as separate groups the Madeiras, Canaries, and Cape Verde Islands. To the west of the great dividing ridge there are two basins. The northern extends from lat. 60° N. to 10° N., widening considerably within the tropics and occupying the great bight between North and South America. In this basin the island of Bermuda rises abruptly from a base only 120 miles in diameter. The southern begins a few degrees to the south-eastward of the last, and extends far into the Antarctic basin. The mean depth of the Atlantic is estimated at 2000 fathoms, and the deepest sounding yet obtained was a little north of the Virgin Islands in 3875 fathoms. The mean depth of the Pacific Ocean is thought to be 3880 fathoms. The greatest depth sounded by the 'Challenger' was 4575 (27,450 feet) at a spot about 1400 miles south-east of Japan, near the Ladrone group. The United States' ship 'Tuscarora' obtained a sounding off the east coast of Japan deeper than this, namely, 4655 fathoms; but there may be a little uncertainty as to this, no bottom specimen having been brought up. The bed of the Pacific slopes to its greatest depths very gradually, being but little broken by submarine ridges, except in the neighbourhood of volcanic islands. Off the Hawaiian Islands, there are submerged mountains as high as 12,000 feet. It is inferred that the bed of the North Pacific sank rather rapidly, as dead coral has been found on some of the submerged peaks, showing that they went down more rapidly than the coral could grow upwards. From recent calculations it would appear that the total area of the ocean is 143,703,000 square miles, and its mean depth about 1877 fathoms, or 0·4624 of a geographical mile. The mean height of Europe above the sea's level is estimated at 300 metres, of Asia and Africa 500 metres, of America 330 metres, and of Australia 250 metres: the mean being 420 metres. The surface ratio of land to water is considered to be 1 : 2·75. The entire bed of the ocean between the depths of 500 and 2250 fathoms is covered with a grey calcareous paste, soft above, stiffer below, and chiefly composed of the minute shells, both entire and in a state of decay, of Foraminifera belonging to the genera Globigerina, Orbulina, and Pulvulina. This is the Globigerina ooze, which has been styled modern chalk, since, if solidified, it would assume very much the appearance of our chalk deposits. Below the depth of 2250 fathoms, this ooze gradually passes into a pure red clay, consisting of silicate of alumina and red sesquioxide of iron in a state of extreme tenuity. This clay is found at the greatest depths yet sounded, and it is supposed to consist chiefly of the insoluble residuum of the foraminiferous shells after all the calcareous portion has been dissolved by the carbonic acid in the sea-water. At depths below 4000 fathoms the red clay is largely composed of the silicious tests of Radiolaria (*St*). Great quantities of pumice are found to be scattered over the bottom of the sea, not only in the neighbourhood of volcanic vents, but also on the bottom of the open ocean. Its disintegration is thought to contribute a constituent to the red clay. Nodules of manganese and iron are likewise brought up by the dredge, the metals being perhaps derived from submarine sources. To account for the vast mass of cold water, often upwards of 2000 fathoms in thickness, at the bottom of the Atlantic, Pacific, and Indian Oceans, two hypotheses have been put forward, both involving a general movement in the mass of the water. The first is, that of Sir Wyville Thomson, who says that the bottom water of the great oceans is an extremely slow indraught from the southern icy sea; and this indraught he attributes to an excess of evaporation over precipitation above the northern portion of the land hemisphere, whilst over the water hemisphere, particularly its southern portion, the reverse is the case. Thus, one part of the general circulation of the ocean is carried on through the atmosphere; the water, being raised in vapour in the northern hemisphere, is hurried by upper wind-currents to the zone of low barometric pressure in the south, where it is precipitated in the form of rain or snow. According to Dr. W. B. Carpenter, however, the *primum mobile* of oceanic circulation is the excess in the specific gravity of polar water which causes its continual descent, whilst there is a complemental ascent of the water in the equatorial zone. In other words, the disturbance of hydrostatic equilibrium is produced by an increase of density occasioned by polar cold and a reduction of density occasioned by equatorial heat. In this way there is an underflow from the poles to the equator, and an overflow from the equator towards the poles. Thus, every drop of water will be brought up from the greatest depths to the surface, except in confined seas. The greater part of the supply of cold water comes from the south polar regions in which direction the oceans are open, whereas the north polar ocean is much enclosed by land, and its water can only make its escape southward by a few comparatively narrow channels. This latter hypothesis seems to satisfy those physicists whose opinion is entitled to most weight. This general circulation of the water in the great oceans is complicated by surface currents caused by winds and the shape of the great continents In the Mediterranean there is a surface inflow through the Straits of Gibraltar, owing to the excess of evaporation over the supplies afforded by rain and rivers, and at the same time an under outflow through the same strait, owing to the greater salinity and therefore greater specific gravity of the lower water of the Mediterranean over that of the Atlantic. The *brine* of the ocean contains besides common salt (chloride of sodium), magnesia, soda, lime, sulphuric acid, and other substances. It forms on the average about 3½ per cent. of sea-water. And it has been calculated that if all the water was evaporated there would remain a deposit of solid matter to the thickness of 350 feet all over the bed of the ocean; and this would correspond to a deposit of 200 feet thick over the entire surface of the globe. With regard to carbonate of lime the analysis of numerous samples of sea-water from different regions and different depths gives a mean result of 0 269 parts of the carbonate in 10,000 parts of water (that is, about 27 parts in a million). Besides these solid matters, carbonic acid, oxygen, and nitrogen are diffused through the ocean It was ascertained that with regard to oxygen, the amount continuously decreases from the surface down to 300 fathoms, whilst from that depth to the lowest yet sounded the amount increases. This curious fact is thought to be due to the great abundance of animal life at the depth of 300 fathoms, and to the comparative scarcity of animals at greater depths, the oxygen therefore remaining unconsumed. It has been found that *light* produces no effect on sensitised paper at the depth of 60 fathoms. Now, although some animals have been discovered without eyes dwelling at various depths, other animals with enormously large eyes have been brought up from very deep water, and it has been suggested that the phosphorescence of zoophytes may afford some light at those depths. The green *colour* of shallow sea-water is believed to be caused by the suspension in it of minute particles of solid matter, whilst the dark blue colour of deep water arises from the comparative absence of such matter, and if it were entirely absent the water would probably be as black as ink.

OCCLUSION (*occlusus*, shut in: *Lat.*). When a gas is absorbed by a metal without combining chemically therewith, it is said to be occluded. For example, if a mass of hot platinum be immersed in hydrogen, a large volume of the gas will be occluded.

ODIN, or WODEN, the chief deity of the Scandinavians. He, his wife Frigga, and son Thor, have given names to three days of our week, the names for Tuesday and Saturday being supplied by the gods Tyr or Tiro, and Sætere.

ODONTOGRAPH (*odons*, *odontos*, a tooth; *graphe*, writing: *Gr.*), in Mechanics, an instrument for designing the teeth of wheelwork.

OHM, a term employed by electricians in calculating the resistance encountered by an electrical current in its passage through a wire. One ohm is the unit of resistance, and is equivalent to the resistance of 250 feet of copper wire one-twentieth of an inch in diameter. Ohm was a celebrated German electrician.

OIDIUM. [See MILDEW (*St.*).]

OLD MAN'S BEARD, the *Tillandsia usneoides* of botanists, nat. order *Bromeliaceæ*. It grows upon the branches of trees in tropical America, and hangs down in long white threads so as to resemble a lichen rather than a flowering plant. It is only used as a packing material, but its singular appearance attracts the attention of travellers.

OLEOMARGARINE [see FAT and MARGARIC ACID], a substance manufactured in North America from the fat of cattle, and largely imported into this country under the name of butterine for the adulteration of butter.

ONOMASTICAL ORDER (*onomastikos*: *Gr.*), an arrangement of words, &c., according to the meanings or matter, not in alphabetical order.

ONTOGENESIS (*on*, *ontos*, a being; *genesis*, generation: *Gr.*), the mode of development of the individual. [See PHYLOGENESIS (*St.*).]

ORES OF METALS. The following is a summary of the various ores of the principal useful metals, and of the modes of extracting the metals from them.

Gold is always found in a metallic state, and is extracted from the extraneous matter, sand, mud, &c., with which it is mixed, by washing with water, or by amalgamation with quicksilver, or with melted lead, which dissolves gold like mercury. To get rid of the lead, the process of cupellation is employed, by which oxide of lead is formed, and this is removed in a liquid state, or it falls into the porous bed on which the alloy is treated. Alloys of gold and silver are treated with sulphuric or nitric acid, of which the silver is converted into a sulphate or nitrate. Gold may be refined by forcing into the melted metal a current of chlorine, which converts the silver, antimony, &c., into chlorides.

Silver is usually found in the state of a sulphuret, and frequently along with galena, a sulphuret of lead. Chloride of silver is abundant in Chili and Peru. Much argentiferous galena is treated first by Pattinson's process, by which the lead crystallises out, and the remainder of the alloy, holding a largely increased percentage of silver, is cupelled. In Mexico the ore is converted into a chloride, and then treated with mercury to form an amalgam. For amalgamation, however, are sometimes substituted other processes, such as (1.) roasting with common salt, to form a chloride, from which the silver is obtained, causing metallic copper to combine with the chlorine. (2.) Roasting the sulphuret, mixed with the sulphurets of copper or iron, so as to form a sulphate of silver, which may be dissolved out with water, and the metal is then precipitated by means of metallic copper.

Copper is found native, in the state of oxides (red copper ore and black oxide), in the state of sulphurets (copper glance, copper pyrites, indigo and peacock copper), also as a sulphuret combined with the sulphuret of antimony and arsenic (grey copper ore), and as a carbonate in the form of malachite. The ores are roasted to expel the arsenic and sulphur, and to convert the iron into an oxide. It is then melted to remove the oxide of iron, and to obtain a sulphide of copper. Lastly, it is roasted and melted to obtain metallic copper.

Iron has numerous ores: magnetic iron ore, red hæmatite, and micaceous hæmatite or specular ore, all of which are oxides; brown hæmatite, an hydrated oxide; spathic iron ore, clay ironstone, both of which are carbonates; blackband ore, a carbonate with clay and bituminous matter; iron pyrites, a sulphuret.

Lead is found as galena, a sulphuret, and as white lead ore, a carbonate. The sulphuret is first roasted in a reverberatory furnace, to convert a part of it into an oxide and part into a sulphate. These being melted, the gas and acid are driven off, and the lead is left in a metallic state.

Mercury is largely found in the metallic state. Cinnabar is a sulphuret, from which the metal is obtained by distillation.

Tin is found as an oxide called tinstone. After calcining to expel arsenic and sulphur, the metal is obtained by smelting.

Zinc; its ores are blende, a sulphuret; red zinc ore, an oxide; and calamine, a carbonate. After calcination, so as to obtain an oxide, the metal is obtained by distillation.

ORMUZD, the good deity who was opposed by the evil deity Ahrimanes, in the dualistic faith of the followers of Zoroaster. A strife is continually going on between these two deities, and hence the mingling of good and evil in the lot of man, but in the end Ormuzd will triumph. This form of the name is Sanscrit; it also appears under the forms of Ormazes, Ahuramasda, &c.

ORTHOGONAL (*orthos*, right; *gonia*, an angle: *Gr.*), a term applied to rectangular or right-angled figures.

OSAGE ORANGE, the fruit of a tree, *Maclura aurantiaca*, nat. order *Urticaceæ*, growing in North America. It is of the size of a large orange, has a yellow exterior, and is filled with a fœtid yellow juice. It is not used as an article of food. The yellow wood is useful, being fine grained and elastic. The dyewood called fustic is obtained from another species of Maclura (*M. tinctoria*), a native of America and the West Indies.

OTHEOMETER. [See RADIOMETER (*St.*).]

OTOLITES (*ous*, *otos*, an ear; *lithos*, a stone: *Gr.*), calcareous accretions of various shapes which are formed in the ears of fishes, and assist in transmitting sonorous vibrations to the auditory nerve. They are often brought up in the dredge with other things

OTTO OF ROSES. In European Turkey the mode of manufacture is this:—Fresh-blown roses are gathered in the rose plantations before sunrise, and immediately placed in a still with water. The liquid that comes over is rose-water, and this is again subjected to distillation, when the otto is obtained. It takes about 28 cwt. of roses to obtain 1 lb. of otto.

OXGANG, in old English, signified as much land as an ox could go over with a plough during the season, estimated at from 15 to 20 acres

OXYHYDROGEN BLOW-PIPE. The light emitted by the flame of hydrogen is very feeble, but the temperature of the flame is very high. A mixture of oxygen and hydrogen affords a solid flame of great heat and peculiar appearance, which, by taking due precaution, may be employed with a blow-pipe to melt refractory substances. A thick piece of platinum, for instance, will readily melt, and a piece of hard steel will burn away in a shower of sparks. Lime, magnesia, and other incombustible bodies glow with an intense light, and can be employed when brilliant illumination is needed, as in the solar microscope instead of the sun's rays.

OZOKERITE, the name of a mineral hydro-carbon, from which paraffin can be obtained by distillation.

P

PADDY, the commercial name of unshelled rice.

PÆDAGOGY (*paidagogia*, instruction of youth: *Gr.*), the art and science of teaching young persons. In Germany they have discovered a theory of education constructed out of the pure Reason.

PALÆOCRYSTIC SEA (*palaios*, ancient; *krustallos*, frozen: *Gr.*), the North Circumpolar Ocean.

PALÆOLITHIC. [See STONE AGE (*St.*).]

PALI (*pali*, a line or row: *Sanscrit*), a language in which the sacred literature of the Buddhists of Ceylon is written. It was derived from the Sanscrit, and was a spoken tongue in India 600 years B.C. The Singhalese, or modern dialect of Ceylon, is a modification or corruption of it

PALMS. [See p. 528.] Besides the palms previously mentioned, there are many others of this noble tribe which are of great utility to man. From the juice of several species a coarse sugar called jaggery is obtained in the Indian Archipelago, Ceylon, and India. Several other species are called Cabbage Palms, from the terminal bud or cabbage being cooked for food. By cutting off the central mass of unopened leaves, the tree is unfortunately killed. The best known of these palms is the *Areca oleracea*, a handsome tree that sometimes becomes 200 feet high, and has leaves 20 feet long. Other palms yield the article known in commerce as DRAGON'S BLOOD. Fatty matters are obtained from the fruit of several species, such as the Oil Palm, an *Attalea* growing in Honduras; the Great Macaw Tree (*Acrocomia sclerocarpa*) of the West Indies and Brazil; and the still better known PALM OIL TREE of the West Coast of Africa. It is the pulpy matter surrounding the nuts which yields the palm oil of commerce. The fruit is first bruised into a paste, and then boiled in water, when the oil rises to the surface. It remains liquid within the tropics, but solidifies to the consistence of butter when taken to a cool climate. Another oil is obtained from the kernels of the nuts, but it is only used by the natives. From some palms wax is obtained. Others yield useful fibres called COIR, PIASSAVA, and *Crin Végétale*, or Vegetable Hair, the last being obtained from the Dwarf Palm (*Chamærops humilis*) of Algeria. Under IVORY, VEGETABLE, it will be seen that an ivory-like substance is obtained from a palm. One of the most important of the family is the Palmyra Palm (*Borassus flabelliformis*) of India and Ceylon. The fan-shaped leaves are used for a hundred different purposes, the wood takes a high polish and is durable, from its juice wine and sugar are made, and the young plants are used as pot vegetables. The Nipa Palm is another very useful tree growing in brackish swamps in Borneo and the Moluccas. Its nuts are like large rough cannon balls; abundance of closely allied nuts are found fossilised in the London Clay.

PANAMA HATS are made of the leaves of a tree (*Carludovica palmata*, nat. order *Pandanaceæ*) which grows in Ecuador, where the hats are principally manufactured. The leaf is cut before it begins to open, and the base forms the middle of the crown of the hat. The mid-rib is rejected, and the rest is divided into narrow strips, which are plaited together. Each hat is made of a single leaf. One of the finest quality occupies the maker for some months, and commands a very high price, but it is very durable

PANGENESIS (*pan*, all; *genesis*, generation: *Gr.*), the doctrine that the formative property by virtue of which organic beings are generated, resides in the living substance of every organised cell and in each of its component molecules, and is a necessary part of the physical and chemical constitution of the organising elements in the conditions of life.

PAPIN'S DIGESTER. [See DIGESTER.]

PAPUAN, a blackish race of men inhabiting the Fiji Islands, the Gulf of Papua in New Guinea, and some intermediate islands in the South Pacific. They are physically well developed, have skin of peculiar hardness or harshness, abundant beard and wiry hair, much frizzled. Each hair, if examined with a lens, is seen to be flattened. Their features are not prominent. They are quite distinct, both from Negroes and the Malayan islanders. The black natives of Tasmania (of whom the last, a woman, died in 1876) were allied to the Papuan races, and were distinct from the chocolate-brown Australians.

PARTICULARISM (*particula*, a small part: *Lat.*), the doctrine of those who maintain that separate interests ought to be supported; a word employed in Germany with reference to the opinion that the separate States of the Empire ought to enjoy as much independence as possible, that is, that their several governments should be carried on with the least possible control of the Imperial Government.

PASHT or **BUBASTIS**, an Egyptian goddess, one of the children of PHTAH (*St.*). She is represented as having a cat's head surmounted by a disc encircled by the viper or [illegible]eus.

PAX (peace: *Lat.*), a small tablet with a crucifix in front and a handle at the back, offered to the lips of communicants at the celebration of the Mass. It is sometimes of precious metal, set with precious stones, enamelled or otherwise ornamented.

PEHLEVI or PUHLAVI. [See PERSIAN LANGUAGE (*St.*).]

PELASGIANS. 'Greek writers from Homer and Hesiod downwards mention Pelasgians, but if we examine their statements we find that the term is used in two senses: firstly, as denoting a certain Greek tribe which inhabited Thessaly during the heroic age; and secondly, as equivalent to our term prehistoric. The name is more especially applied to the natives of Thrace, who seem to have belonged to the Illyrian stock. In modern times it has served as the watchword of all kinds of obsolete theories and prescientific fancies. We know nothing about the Pelasgian language' (Professor A. H. Sayce). There seems to be no certain evidence that any Pelasgian tribe settled in Italy.

PELORISATION (*pelorios*, monstrous: *Gr.*), in Botany, the property of assuming an exceptional and unusual form. Thus a flower which has five stamens instead of the normal number of four, is a pelóric flower.

PEPSINE (*peptein*, to digest: *Gr.*), a nitrogenous substance existing in the gastric juice, and as a viscid matter in the peptic gland and on the walls of the stomachs of animals. This is extracted from the stomachs of the hog, sheep, or calf, and made into various preparations taken as remedies in cases of defective digestion.

PERPENDICULAR STYLE, in English Gothic Architecture, or, as it is sometimes called, the Third Division of the Pointed Style, was employed from the latter end of the fourteenth to the early part of the sixteenth century. The tracery of the windows exhibits perpendicular and horizontal lines. The doorways have four centred arches and horizontal lines; the groinings are decorated with fanlike tracery; and the surfaces of the buildings are enriched with upright forms of panelling. Henry VII.'s Chapel at Westminster Abbey, St. George's Chapel, Windsor, and King's College Chapel, Cambridge, are three striking examples of this style.

PERPETUUM MOBILE (perpetual motion: *Lat.*). [See PERPETUAL MOTION.]

PERSEIDES, a name of the meteoric shower of the 10th of August, so called because it appears to issue from the star Algol in the constellation Perseus.

PERSIAN LANGUAGE, the most important of the Iranic tongues. The ancient Persian is only known from some inscriptions. The middle Persian, or Pehlevi, was the language of the epoch of the Sassanides, from the third to the seventh century; then came the Parsee, and afterwards (since the year 1000) the modern Persian. This contains many Arabic words.

PERTURBATIONS, in Astronomy, those deviations of the heavenly bodies from their elliptical paths which take place in consequence of their mutual attractions. The *periodic* perturbations are those which are compensated after a limited number of revolutions and then begin again; these are called inequalities depending on configurations. The *secular* perturbations require a great length of time for their consummation, and before they recommence their long periods. The motions of the moon display the most considerable perturbations.

PHALANSTERY, in the system of the French socialist Fourier, the common residence and collected workshops of a phalanx—that is, 400 families.

PHENOL, PHENYLE, names given to CARBOLIC ACID (*St.*).

PHILIPPIUM, a rare metal lately found by M. Delafontaine, in the Samarskite earth of North Carolina, named after a physicist of Geneva. Its equivalent is 74.

PHONAUTOGRAPH (*phone*, sound; *autos*, itself; *graphe*, writing: *Gr.*), in Acoustics, an instrument for graphically representing the vibrations of a sonorous body. It also affords a means of counting the number of vibrations in a given time. The vibrations required to be represented are made to affect the air inside an apparatus which is something like an ear-trumpet, across the narrow end of which is stretched a membrane. To this membrane is attached a marking style, which is brought into contact with a piece of smoked paper placed upon a cylinder capable of being moved both horizontally and round its axis. When the vibrating body is set in motion the membrane vibrates in correspondence, and the style draws a tremulous line upon the paper upon the cylinder, the latter being at the same time made to move by turning a handle which works a screw.

PHONOGRAPH (*phone*, sound; *graphe*, writing: *Gr.*), an apparatus invented by Mr. T. A. Edison, of New York, by means of which it is said that 'words spoken by the human voice can be stored up and reproduced at will over and over again hundreds of times.' It consists of three parts—a receiving, a recording, and a repeating apparatus. The first is a tube into which the words are spoken, at the farther end of which is a thin metal diaphragm, having a small pin attached to its centre. The second part consists of a cylinder capable of being revolved on its axis, and having a coat of tin foil which the pin just touches. This cylinder being made to revolve slowly whilst the vibrations caused by the speaker's voice, first in the air of the tube, and then in the diaphragm and its attached pin, drive the latter against the tin foil, where they make a series of indentations. The words being thus printed upon the strip of metal, their sound having been converted into a visible form, the next step is to reconvert them into sound, and for this purpose the third part of the apparatus is employed. This consists of a tube, one end of which is covered with paper stretched taut. Upon this paper plays a pin attached to a steel spring, which, being brought into connection with the pin of the receiving apparatus the whole is ready for action. Now if the motion of the cylinder be repeated in such a way as to cause the pin of the transmitting part to pursue its former path, and to fall into the series of indentations it had previously made, the vibrations thereby caused in the attached metallic diaphragm are conveyed to the steel spring, repeated by its pin upon the paper diaphragm, and conveyed along the tube to the ear of the listener.

PHONOGRAPHY (*phone*, sound; *graphe*, writing: *Gr.*), the system of writing words phonetically—that is, in the way they are pronounced, one unvarying sound being given to each letter. The sounds of the English alphabet and the spelling of the words being extremely irregular, many attempts have been made to introduce a system of phonography. [See LETTERS (*St.*).]

PHOTOGRAVURE, a French process for etching a design which has been first drawn on the metal by a photographic method.

PHOTOHELIOGRAPH (*phos*, light; *helios*, the sun: *Gr.*), an apparatus for obtaining photographic pictures of the sun's surface. The sun is thus made to take his own likeness.

PHOTOSPHERE (*phos*, light; *sphaira*, a ball: *Gr.*), the visible surface of the sun.

PHTAH, the creator of the world in Egyptian Mythology, especially worshipped at Memphis. He was usually represented as a man with a cap fitting tightly to his head, holding or leaning against the Nilometer, the emblem of stability. The scarabæus was also his symbol.

PHYLLOTAXIS (*phullon*, a leaf; *taxis*, order: *Gr.*), in Botany, the arrangement of the leaves on a branch; thus, leaves are sometimes opposite, sometimes spirally arranged.

PHYLLOXERA (*phullon*, a leaf; *xēros*, dry: *Gr.*), a small insect, the *Phylloxera vastatrix* of entomologists, belonging to the family of Aphidæ, which, originating in North America, has got into the vineyards of Europe, where it has done and is doing immense damage. The French Government has offered a large reward to the discoverer of a cheap and easy remedy against its ravages. The insect is at first yellow, and afterwards greenish. It has an oval shape, and is furnished with six legs, a proboscis, and a pair of antennæ. Whilst wingless it passes the winter at the root of the vine, and in the spring attacks the fibres, into which it bores with its proboscis. It lays from thirty to forty eggs, which are hatched in eight days, and the young insects in a short time proceed to lay eggs which are hatched in the same way, a case of PARTHENOGENESIS. In the course of the summer there are from six to eight generations, and thus a single female may be the ancestor in a few months of thirty millions of individuals. Some individuals of the later broods creep up the stem into the air. Each of these receives two pairs of long wings, and lays four eggs, which produce males and females. Each of the latter, after impregnation, lays in the bark of the vine a single large egg, from which an insect is hatched in the spring. This attaches itself to the roots of the vine, and the same round is gone over again. Sometimes the wingless insect lives in little galls on the under side of a leaf. Such is the curious history of this destructive insect. Its attacks cause the fibres of the root to swell into knots and knobs; they then decay, the plant becomes sickly and finally dies. It is the general opinion that the American vines do not suffer so severely from Phylloxera as European vines, and the former have been largely imported for the purpose of being planted as stocks for grafting.

PHYLOGENESIS (*phule*, a race or tribe; *genesis*, generation: *Gr.*), the mode of evolution of a race or organic type, for example, the vertebrate type. It is affirmed by anatomists that there is a correspondence between the development of the individual [ONTOGENESIS (*St.*)] and that of the race. The history of the formation of the vertebral column is pointed out as a good example of this correspondence, for all the stages which occur in the gradual evolution of that osseous system in the series of vertebrate animals, are repeated in the successive stages of the embryonic development of the higher members of the series. Again, Professor Allen Thomson states that the study of the comparative anatomy of the heart and its mode of formation in the embryo furnishes most striking illustrations of the relation between ontogenetic and phylogenetic development in the vertebrates. The final generalisation is that the ontogenetic development of the individual in the higher animals repeats in its more general character, and in many of its specific phenomena, the phylogenetic development of the race.

PHYSIC NUT, the fruit of the *Jatropha curcas* (or *Curcas purgans*), nat. order *Euphorbiaceæ*, which is cultivated in tropical countries for the sake of its oil, which is purgative, and is used for burning in lamps. The Chinese make a black varnish by boiling the milky juice of the plant with oxide of iron.

PHYSIOGRAPHY (*phusis*, nature; *graphe*, writing: *Gr.*), any description of the powers and processes of nature.

PIBROCH (*Gaelic*), martial music played on the bagpipes, not the instrument itself.

PICRIC ACID (*pikros*, bitter: *Gr.*), may be obtained by the action of nitric acid on indigo and numerous other substances, such as silk, wool, salicine, &c It forms pale yellow scaly crystals, which are sparingly soluble in cold water, and possess an intensely bitter taste. Picric acid is used in dyeing.

PIGEON PEA, the pulse of a leguminous plant, *Cajanus Indicus*, which is largely cultivated in tropical countries as affording a nutritious esculent. In India the pulse is called Dhal.

PIPUL or PEEPUL, the *Ficus religiosa* of botanists, the Sacred Fig of India, round which many superstitions cluster. The leaf is remarkable for having its apex drawn out into a long point. It is the custom of the Hindoos to plant two of these trees near together with a Neem tree (*Margosa*) between, and to go through an elaborate ceremony of marrying the pipuls.

PISCINA (a pool or cistern: *Lat.*), a stone basin or small trough with an outlet at the bottom, placed near the altar in churches. Amongst the ancient Romans piscina signified both a fish pond and a swimming bath.

PLANETS. The masses of *Uranus* and *Neptune* have been recently calculated by Professor Newcomb to be respectively the 1-22,600th and 1-19,380th of that of the sun. *Jupiter's* mass is equal to 1-1047th of the sun's. The time of the rotation of *Saturn* has been newly determined to be 10h. 14m. 24s. The existence of a planet between Mercury and the sun has been suspected and much searched for, but hitherto without success. It has been ascertained that *Venus* has an atmosphere. Her light at its greatest brilliancy is equal to about 1-800th of the light of the full moon.

PLANTIGRADES (*planta*, the sole of the foot; *gradiri*, to walk: *Lat.*), a tribe of carnivora, which in walking place the sole of the foot on the ground. It includes the bear, badger, racoon, common otter, and sea-otter.

PLANULA (*planus*, flat: *Lat.*), in Zoology, the ciliated larva of a hydroid zoophyte.

PLATYRRHINE (*platus*, broad; *rhin*, the nose: *Gr.*), a term applied by anthropologists to races of man with broad noses, *e.g.*, the negroes. The monkeys of the American continent are platyrrhine. [See CATARRHINE.]

PLEXUS (interwoven: *Lat.*), in Anatomy, the networks of nerves which are found in several parts of the body.

PNEUMATIC TUBE, a subterranean tube constructed for the transmission of articles from one place to another. The articles are placed in a receptacle which exactly fills the width of the tube, and the motion is effected by exhausting the air in front of it, or forcing in compressed air behind it. There are pneumatic tubes in use between the General Post Office, London, and some of the railway stations.

POLAR DISTANCE, in Astronomy, the angular distance of a star or point in the heavens from either the north or south celestial pole. Polar distance and declination are complementary.

POLYCHROMY (*poluchromos*, many coloured: *Gr.*), the property of having many colours; often used with reference to the buildings and sculptures of ancient Greece, which it is known were coloured. *Polychromatic*, having many colours, in opposition to *monochromatic*, having only one.

POLYGONACEÆ (*polygonon*, knotgrass: *Gr.*), an order of monochlamydeous plants, chiefly herbs or shrubs, distributed all over the world. The genera *Fagopyrum* (Buckwheats), *Rumex* (Docks and Sorrels), and *Rheum* (Rhubarbs), as well as many common weeds, belong to this order.

POLYHISTOR (a learned man: *Lat.*), the title of a compendium of geography containing a sketch of the world as known to the ancients; written by C. Julius Solinus, who flourished about A.D. 238. Also a title given to the grammarian Cornelius Alexander, who, when a soldier in the army of Mithridates, was taken prisoner by Sylla and brought to Rome as a slave. He received his freedom on account of his learning, and became rich. Only fragments of his works remain.

POLYMORPHISM (*polus*, many; *morphe*, form: *Gr.*), the property of having several forms.

POST OBIT (*post obitum*, after death: *Lat.*), a term applied to an instrument such as a bond, which is not to take effect or be enforced until after the death of a person living at its date.

PRAKRIT, a name given by Oriental scholars to any Aryan vernacular tongue in India. The Hindi, Punjabi, Sindhi, Gujarati, Marathi, Orija, and Bengali are the principal Prakrit languages.

PRECONISATION (*preconiatio*, high commendation: *Low Lat.*), the ceremony which takes place at a consistory of cardinals at Rome, when an ecclesiastic is proposed by the Pope to fill the office of bishop. To preconise formerly meant to summon into court, *voce præconis*, by the voice of the public crier.

PREDELLA (a footstool: *Ital.*), the row of little pictures often placed by the old masters at the foot of a large picture.

PREFET (*Fr.* from *prefectus*: *Lat.*), in France the chief civil official of a department, acting under the orders of the Minister for the Interior. The corresponding official in Italy is styled Prefetto.

PRESTER JOHN, a mythic king of the Middle Ages ruling in Abyssinia or Ethiopia. He was supposed to be a Christian and to derive his name Prester from priest as having converted his subjects.

PRIMULACEÆ, in Botany, a natural order of plants, with monopetalous flowers, containing some ornamental garden plants (primula, polyanthus, auricula, cyclamen, &c.), and some well-known wild plants (the primrose, cowslip, pimpernel, &c.), but none of any marked utility. The Chinese primrose, *Primula Sinensis*, is much cultivated. Polyanthuses are distinguished by gardeners into pin-eyed when the pistil projects and the stamens are very short, and thrum-eyed when the pistil is very short and the stamens conspicuous.

PROLETARIAN. The sixth and poorest class of the citizens of Rome, in the constitution ascribed to Servius Tullius, were called *proletarii*, because their only means of aiding the state was by their offspring (*proles*). At present the term proletarian is applied to the class of work-people without capital.

PRONAOS (*pro*, before; *naos*, a temple: *Gr.*), that part of a temple which projected in front of the rest, forming what we now call a portico.

PROPÆDEUTICS (*propaideucin*: *Gr*), preliminary instruction; preparatory science.

PROPYLÆA (*propulaion*, a porch or portico: *Gr.*), the entrance to a Greek temple consisting of an enclosure flanked by buildings with a great gateway.

PROTOPLASM (*protos*, first; *plasma*, material for moulding: *Gr.*), a nitrogenous, hydro-carbon compound, forming the raw material of all animal structure. It is a formless mass of granules and slimy matter, possessing the vital properties of assimilation, irritability, and reproduction. It is the most elementary of all organic substances. The contents of animal cells usually consist of protoplasm. Sarcode, of which some minute animals entirely consist, is composed of protoplasm. [See AMŒBA (*St.*).]

PSYCHROMETER (*psuchros*, cold; *metron*, measure: *Gr.*), a name sometimes given to the combination of thermometers with wet and dry bulbs employed for ascertaining the quantity of moisture in the air at the time of observation. One bulb being kept moist, the mercury falls to a point depending upon the amount of evaporation, and that again depends on the temperature and the quantity of moisture already in the air. The readings of the thermometer and that having the dry bulb afford data for solving the problem. Such a combination of instruments is known on the Continent as August's Psychrometer, and in England as Mason's Hygrometer.

PTERYLOGRAPHY (*pterux*, a plume; *graphe*, writing: *Gr.*), the study of the development, growth, arrangement, &c., of the plumage of birds.

PURBECK STONE, an ash grey sandstone, quarried at Purbeck in Dorsetshire, and much employed by London builders.

PUSHTOO, the language of the Afghans, one of the Iranic tongues.

PYRAMIDION (little pyramid: *Gr.*), the pyramidal top or termination of an obelisk.

PYRHELIOMETER (*pur*, fire; *helios*, the sun; and *metron*, measure: *Gr.*), an instrument devised by Pouillet for measuring the amount of heat radiated from the sun. He computed that the heat received annually by the earth from the sun would be sufficient to melt a coat of ice 98½ feet thick surrounding our globe.

Q

QUALITATIVE, QUANTITATIVE. These words are frequently employed in speaking of chemical analysis. The former signifies that the mere presence of a particular body is sought or has been ascertained; the latter that its absolute or proportionate quantity is the object of research.

QUANTIFICATION OF THE PREDICATE, in Logic, the attaching some word or mark to the predicate of an affirmative proposition to indicate that it is applicable to something besides the subject; in other words, when the predicate is undistributed. For instance, by the proposition, All horses are quadrupeds, it is not intended to assert that the attribute of possessing four legs is confined to horses. To mark this limitation of meaning, Sir William Hamilton, of Edinburgh, proposed to add the word *some*, and to write the proposition in this way: All horses are some quadrupeds.

QUARRY (*carré*, square: *Fr.*), a pane of glass.

QUATERNARY EPOCH (*quaternarius*, four: *Lat.*), in Geology, the modern epoch which commenced at the close of the Tertiary period, and now exists. It is often termed Postpliocene.

QUATERNIONS, CALCULUS OF (*quater*, four times: *Lat.*), a Symbolical Geometry invented by Sir W. R. Hamilton, of Dublin, depending upon four irreducible geometrical elements. 'It is only now beginning to be understood,' says Mr. W. Spottiswoode, 'and has not yet received all the applications of which it is doubtless capable. It must always hold its position as an original discovery, and as a representative of one of the two great groups of generalised algebras, viz., those the squares of whose units are respectively negative unity and zero, the common origin of which must still be marked on our intellectual map as an unknown region.'

R

RA, the Egyptian god of the sun, represented sometimes in the human form with the flesh coloured red, bearing on the head the sun's disc encircled by the viper or uræus, the type of dominion; sometimes by a hawk-headed man surmounted by the atf or high conical cap flanked by ostrich feathers; sometimes by a male sphinx or a hawk.

RACHIS (*rachis*, the spine: *Gr.*), in Botany, the general axis of inflorescence, that is, the primary axis of a spike or raceme of flowers; also, the stem of the frond of a fern above the stipe or stalk.

RADIOLARIA, a division of the Rhizopoda. The animals are marine, and of a low type of organisation. Some species are simple, others compound; some have neither spicula nor shell, whilst others have either silicious spiculæ or silicious shells. The POLYCYSTINA, whose beautiful fossil shells are well known to microscopists, belong to the Radiolarians.

RADIOMETER (*radius*, a ray; *metron*, measure: *Gr.*), an apparatus invented by Mr. W. Crookes, consisting of vanes of pith, each blackened on one side whilst bright on the other, mounted on arms attached to a movable axis, and enclosed in a glass vessel from which the air is exhausted as much as possible. When exposed to the light the axis carrying the vanes begins to revolve. It was at first thought that the motion was caused by the action of light, and hence the apparatus was styled a Light Mill; but it was afterwards found that the motion is due to the action of heat on the molecules of attenuated air still left inside the glass, on these coming into contact with the blackened discs, or, as it has been expressed, the repulsion of the discs results from radiation due to an action of thermometric heat between the surface of the moving body and the case of the instrument through the intervention of the residual air. Mr. Crookes afterwards devised a form in which the heater is stationary and the cooler rotates. This he called an Otheoscope (*otheo*, I propel; *scopein*, to see: *Gr.*).

RAMBUTAN (hairy fruit: *Malay*), the fruit of a tree cultivated in the East Indies, the *Nephelium lappaceum*, nat. order *Sapindaceæ*. The fruit is about the size of a small plum; it grows in clusters, is red and hairy outside with a semi-transparent white pulp, which contains a subacid juice. To the same genus belong two esteemed Chinese fruits: the Leechee, which is produced by the *Nephelium Litchi;* and the Longan, the Long-yen, or Dragon's eye, of the Chinese, the *N. longana*.

RANCHEROS (*Span.*), the cattle-breeding people of Mexico, who are excellent horsemen. They are so termed from their residences called *ranchos*.

RANGE FINDER, in military affairs, an apparatus for discovering the distance of an object from the gun in order that the proper charge of powder may be used. There are many contrivances for this purpose.

RAPPISTS, the followers of George Rapp (d. 1847), a German enthusiast who settled in the United States, and founded the colony known as Harmony, near Pittsburg.

RAPTORES (*raptor*, a robber: *Lat.*), an order of birds of prey, including eagles, falcons, hawks, owls, &c. They have powerful hooked beaks and talons, and great strength of wing. They are divided into diurnal birds of prey with eyes directed sideways, and nocturnal birds of prey with eyes directed forwards.

REACTION, a word borrowed from the French to signify chemical action

RECTIFICATION, in Mathematics, the ascertainment of a straight line equal in length to a given curve.

RECTILINEAL FIGURE, one that is bounded by straight lines.

REED PIPE, in organs and harmoniums, a pipe furnished internally with an elastic metal plate called the tongue, attached at one end and free at the other. By its vibrations it alternately opens and closes an aperture through which the wind is driven and so produces a musical note

REFLEX ACTIONS, in Physiology, are those motions of our bodies which answer to a stimulus without the intervention of the will (being therefore automatic and involuntary), such as the action of the heart, the expansion and contraction of the chest in breathing, and the rapid withdrawal of the hand if suddenly pricked. These and similar actions are believed to be stimulated through the spinal cord and the base of the brain in connection with it, without involving the rest of the brain.

RELAY, in Electric Telegraphy, an apparatus which, on receiving a feeble current from a distance brings into the circuit a much stronger current derived from a battery on the spot Relays are employed in the course of long lines which could not otherwise be worked through from end to end—or when currents arrive at a station too much enfeebled to indicate their purpose clearly without assistance.

RELIQUARY, a case or frame, often richly ornamented, for holding the relics of saints preserved in Roman Catholic churches.

REPOUSSÉE WORK (*œuvre repoussée: Fr.*), ornamental metal-work in low relief, produced by beating the design up from the back by means of a punch and hammer. The work can be afterwards finished by chasing or other process.

S

SACCHAROMETER. [See p. 654.] In order to determine the quantity of sugar in cane or beetroot juice, instruments have been invented by which the test of polarised light can be employed in place of or in addition to the use of a density apparatus.

SACHEM, the chief of a tribe of North American Indians.

SAKI, a spirit distilled from rice by the Japanese, who drink it hot out of small cups

SALICYLIC ACID is the oxide of a compound salt-radical called salicyl, which is composed of carbon, hydrogen, and oxygen. It is in the form of white prisms which have a sweetish-sour taste, and are only feebly soluble in water. It may be obtained from the volatile oil distilled from the flowers of the common meadow sweet (*Spiræa ulmaria*) or from SALICIN. When exposed to a strong quick heat it decomposes into carbonic acid and hydrate of phenol. It is a powerful antiseptic, and is employed for this purpose. The salicylate of soda is employed in medicine.

SAMARIUM, a metal lately discovered by M. Lecoq de Boisbaudran in SAMARSKITE.

SAMARSKITE, a mineral found in North Carolina, remarkable for containing the earths of seven rare metals, viz., Yttria, Erbia, Terbia, Philippia, Decipia, Thorina, and Samaria.

SARACENIC or MOORISH ARCHITECTURE, a peculiar style which received its greatest development in Spain, where many beautiful examples are still to be seen. It is chiefly characterised by the horseshoe arch, the slender proportions and the great number of the pillars, and the profuse use of geometrical ornamentation in mosaics, reliefs, and fretwork upon floors and wall surfaces. A combination of this style with Gothic came to be formed which is very different from the Gothic of Northern Europe. The cathedral at Palermo is often cited as an example.

SARACENS (*Saraceni* in mediæval Lat.), the name given by the Crusaders to their Mohammedan enemies, whether Turks, Moors, or Arabs.

SATIN SPAR, the name given to a fibrous variety of gypsum which when polished has a satiny lustre, and is worked up into beads and other ornamental articles. The name is also applied to a fibrous variety of carbonate of lime for a similar reason.

SATIN WOOD, an ornamental wood used for furniture; that from Ceylon is the wood of the *Chloroxylon Swietenia*, nat. order *Cedrelaceæ*. West Indian satin-wood comes chiefly from the Bahamas, and is now preferred to the East Indian. It is the produce of some species of *Maba*.

SATRAP (*satrapes: Gr.*), the governor of a province in the ancient Persian empire.

SCANDINAVIAN LANGUAGES. These are the East and North German, the extinct Gothic, the Old Norwegian, and the modern Swedish, Norwegian, and Danish; and they form a branch of the German group of the Indo-European tongues. The oldest of the Scandinavian languages is the Old Norwegian, only spoken in some of the remote valleys of Norway and in Iceland, whither it was taken in the ninth century. Scandinavia was the name given by the Romans to this northern part of Europe.

SEMOLINA (a small seed: *Ital.*), a name given to several different articles: a preparation of wheaten flour similar in substance to macaroni and vermicelli; the hard parts of wheat left unground after passing through the mill; the seeds of a grass called *Poa* or *Glyceria fluitans*. *Semola* is said to be the gluten of wheat.

SERENE (*serenissimus* or *serenitas: Lat.*), a title first given in Germany under the form Durchlaucht in 1375, when the Emperor Karl IV. bestowed it on the electors. In the course of time it was given to other reigning princes.

SHEERS, in Engineering, an apparatus employed instead of a crane for lifting heavy bodies. It consists essentially of two inclined spars or beams meeting above the lifting chains working between them.

SHILLING. The following table will show the value of this coin at different periods of our history. Until the year 1300 a pound of silver was coined into 20 shillings, whilst at the present day it is coined into 66.

1066	....£1	0	0	1527	....£2	0	0
1300	 1	0	3	1513	 2	8	0
1349	 1	2	6	1560	 3	0	0
1356	 1	5	0	1600	 3	2	0
1421	 1	10	0	1816	 3	6	0
1464	 1	17	6				

SHINTOOISM, the ancient religion of the Japanese, and still the State religion, but Buddhism and the doctrines of Confucius have been largely adopted by the people. It mainly consists of a belief in spirits.

SINGHALESE, the race forming the principal part of the inhabitants of Ceylon. They profess Buddhism.

SINOLOGUE (*Fr.*), or **SINOLOGIST** (*Sinæ*, the Chinese: *Lat.*), a person learned in the language and literature of China.

SIREN (a sea nymph in Grecian mythology), in Acoustics, an instrument invented by Cagnard de Latour for counting the vibrations of a body producing a musical note. The principle depends on obtaining a series of notes from it by means of air driven through the holes in a circular plate which is thereby made to revolve. The number of revolutions in a given time increases with the pitch of the sound emitted. An axis attached to the revolving plate is connected with a counting apparatus. A note being obtained from it in unison with the note whose vibrations are to be counted is then obtained from it by working a pair of bellows (the unison being ascertained by the operator's ear), and the number of revolutions caused by the particular note in a given time is given by the counting apparatus. The name Siren was fancifully given to the apparatus because sound can be produced by forcing water through it as well as air.

SLAG WOOL, a fibrous material made from the slag of iron furnaces by driving steam or air against a thin current of it, when in a melted state. It can be woven into sheets which are used for coating steam boilers, the substance being a bad conductor of heat. Delicate glassy fibres, very similar to slag wool, are spun by the wind from drops of lava in the crater of Kilauea at the Sandwich Islands, where it is termed Pele's Hair, Pele having been the goddess of fire in the days of idolatry. Analysis shows that it has almost the same composition as a basalt or dolerite.

SLAVS, a race which entered Mœsia and Thrace, from the north in the fifth century. The original *Slavonic* language, a branch of the Indo-European family of tongues, has now seventeen different dialects. Russian, Polish, Servian, Czechian, Bulgarian, &c.

SLIDE VALVES, the valves or moving plates which alternately open and close the orifices by which the steam enters and escapes from the cylinder of a steam-engine.

SNAKE ROOT, the root of a plant, *Polygala senega*, nat. order *Polygalaceæ*. [See SENEGA ROOT.] Other North American plants belonging to the genus *Aristolochia*, are also called SNAKE ROOT.

SNAKE WOOD [see p. 693], a beautiful red wood, variegated with black spots and marks, obtained in tropical South America. It is used chiefly for walking sticks.

SOAP-BERRY, the hard black seed of the *Sapindus saponaria*, a tree belonging to the nat. order *Sapindaceæ*, a native of South America. The fruit is of the size of a cherry, and its pulp can be used instead of soap in washing linen. The seeds are worked up into buttons and beads by the Spaniards.

SOCINIANS, a religious sect, the followers of Fausto Socino, an Italian, born at Siena in 1539. He taught that Jesus Christ had no existence previous to his miraculous birth, and that although he was deserving of the greatest reverence for his teaching and his acts, and as being the appointed medium between God and man, he neither claimed nor possessed the divine nature The modern Unitarians have embraced most of the tenets of Socino

SOROSIS (*soros*, a cluster Gr), in Botany, the name given to a compound fruit formed of a spike of flowers which grow together and become succulent The pine apple and mulberry afford examples of a sorosis In the latter fruit the calyces of many flowers growing close together become succulent and invest the pericarp and seeds

SOTHIAC PERIOD, THE, was used by the ancient Egyptians, and consisted of 1461 wandering years of 365 days, or 1460 fixed years of 365¼ days

SOUND [See p 698] All the conditions as to the transmission of sound through the atmosphere are not yet fully understood, and several facts are still waiting for explanation For instance, when in the course of some experiments a gun was fired at Montlery, it was heard at Villejuif, whilst a gun fired at the same time at Villejuif was inaudible at Montlery Then sound is usually heard farther with the wind than against it but in what manner the audibility of sound is increased or diminished by the action of the wind is not at present clearly defined Again, the increase of audibility produced by wind will sometimes reach several hundreds per cent, when the velocity of the wind has only increased one per cent Sound is often heard better across the wind than with it, and it is thought that there occurs something analogous to the refraction of light Professor O Reynolds has shown that rays of sound in traversing the atmosphere are usually bent upwards owing to the fact that sound travels faster in warm than in cold air, irrespective of density Now as the air is usually warmest near the ground, the lower part of the wave front will advance faster than the upper part, and as the direction of advance is always perpendicular to the front, it will be bent upwards in a curve whose radius will be about twenty miles when the difference of temperature is 1° F

SPECTRUM, SPECTRUM ANALYSIS [See pp 700, 701] In producing the solar spectrum by means of a glass prism, if the refracting edge of the prism is turned towards the ground, then the violet end of the spectrum will be at the top and the red end at the bottom This shows that the red rays are the least refrangible of the visible spectrum, and the violet rays the most refrangible By employing a thermopile and sensitised paper, it is found that the red end has the most heat rays and the fewest actinic rays, whilst the violet end has the fewest heat rays and the most actinic rays, there being a gradual transition in both respects from one to the other It is found, moreover, that heat rays are thrown beyond the visible red end, and actinic rays beyond the visible violet end In the latter case by careful manipulation part of the spectrum beyond the violet may be rendered faintly visible, and then it is seen to be of a lavender grey tint, and to be crossed by dark lines like the more luminous part of the spectrum The luminosity of this part of the spectrum is very weak on account of the absorption which the rays suffer in traversing our atmosphere By a continuous spectrum is meant one like the solar spectrum where the colours meet and pass successively one into another A discontinuous spectrum is one composed of separate bands or lines with blank spaces between The former kind of spectrum is given by an incandescent solid or liquid, the latter by a glowing vapour, whether a permanent gas or derived from a volatilised solid or liquid Such a vapour affords a spectrum of bright lines peculiar to it, so that it can be recognised whenever the lines make their appearance When an incandescent solid or liquid is seen through a glowing absorbent vapour, the spectrum from the solid or liquid is continuous with lines from the vapour across it These lines will be dark if the solid or liquid body is of a higher temperature than the vapour, and bright if the vapour has the higher temperature If the solid or liquid body and the vapour have the same temperature, the lines will vanish because the vapour will emit as much light as it absorbs The spectrum of the electric spark is a bright line, one made up of the spectra of the vapours between which and through which the spark passes By subjecting the vapour operated upon to pressure, the lines, in the case of some chemical elements, are thickened, and in the case of others, are increased in number By varying the pressure or increasing the temperature, different spectra can be obtained from the same element Thus, in the case of iron, the lines may be increased from one to 460, and in the case of calcium two wholly distinct spectra have been obtained, one pertaining to a low, the other to a high temperature The largest drawing of the solar spectrum that has hitherto been obtained was thirty metres long, from A to H, and it comprised 4000 lines Some results obtained by means of the spectroscope are stated under SUN and NEBULÆ

SPIROMETER (*spiro*, I breathe · *Lat*; *metron*, a measure *Gr.*), an apparatus for measuring the quantity of air given out by the lungs after taking in a long breath. It is employed by medical men to ascertain the lung capacity of a patient.

SPIRULA (a little coil: *Lat.*), in Zoology, a genus of ten-armed cuttle-fishes furnished with a shell which is almost covered by the body. The shell is small, white, and many chambered, curled into a flat spiral. It is thrown by thousands on some islands in the Atlantic and Pacific Oceans, but only five specimens of the animal have been seen by naturalists.

SPLINT, a hard excrescence which forms on the shank bone of a horse.

SPONTANEOUS GENERATION. All the evidence hitherto adduced in support of the hypothesis of what is popularly termed spontaneous generation has been shown to be valueless, but it has not by any means been proved, and it would be very difficult to prove, that the lowest forms of life may not be naturally generated when the suitable inorganic materials are brought together under suitable conditions of temperature, pressure, &c., in places not easily accessible to direct observation—at the bottom of the ocean, for instance. We are not to conclude, because proof has not so far been produced, that it cannot be produced at some future time. So to conclude would be bad reasoning, of a character which the progress of geology and astronomy has again and again exposed. The hypothesis of spontaneous generation is not of the nature of a superstition, but is a purely physical one, against which there is no *a priori* impossibility. In the present state of science it is rather one to be styled probable. Proof of the fact is wanting, and that is all. On the one hand, the fact is not to be asserted without full and complete proof; on the other, it is not to be declared an impossibility because it has not yet been proved.

SPORES, RESTING, the oogonia or germs of minute parasitic fungi, such as the potato fungus, the *Phytophthora infestans* of botanists. After being fecundated by the smaller bodies called antheridia, they are rendered capable at the end of a period of rest to germinate and produce new fungus threads which spread through the tuber and render it useless, or to form minute movable sporules or zoospores contained in cases.

SQUARES, LAW OF INVERSE, a law applying to light, heat, sound, and other physical phenomena, which is thus expressed: The intensity of the light, &c., received from any source varies inversely as the square of the distance.

SQUARES, METHOD OF LEAST, one of the most useful applications of the calculus of probabilities, the object being to obtain the most probable result from a number of observations which have given different results though all are believed to be equally trustworthy.

SQUASH, the name given in the United States to the numerous varieties of pumpkin, *Cucurbita melopepo*, cultivated for table use.

STAFF, in Music, the five horizontal lines on or between which the notes are placed.

STANNITE (*stannum*, tin: *Lat.*), an ore of tin, the oxide.

STICHOMETRICAL (*stichos*, a rank or row: *Gr.*), a term applied to an arrangement according to the subject-matter, not alphabetical.

STIGMARIA (*stigma*, a mark or spot: *Gr.*), the roots of fossil trees belonging to the genus *Sigillaria*, characteristic of the Carboniferous period, and believed to be related to Cycads. Stigmariæ were long thought to be distinct plants until the roots were discovered in connection with the stems of Sigillaria. The peculiar markings on the roots gave origin to the name.

STILUS (*Lat.*), the small iron rod employed by the Romans for writing upon tablets coated with wax. One end was sharp for tracing the letters, and the other end was made broad for erasing, when desirable, what had been written. Hence Horace recommends a writer for the public to turn his stilus frequently. The stilus was therefore an ancient pen, and the word came in time to signify the composition or manner of writing; whence our word *style*.

STŒCHIOMETRY (*stoicheion*, a first principle: *Gr.*), that branch of Chemistry which is concerned with the laws of the combination of bodies by weight and volume. [See AFFINITY.]

STOMATA (mouths: *Gr.*), in Botany, minute openings through the epidermis of the leaves of plants. The opening is usually between a pair of semi-lunar cells. It is supposed that the office of the stomata is to regulate the evaporation from the chlorophyll of the leaf, becoming larger or less according to the hygrometrical state of the atmosphere.

STONE AGE, in Anthropology, that period in the history of a people when their only cutting implements were made of flint, obsidian, or other stone. Ancient implements of this kind are often found in caves or buried in river gravel in various parts of Europe. Two periods have been distinguished. In the earlier (termed *palæolithic*, from *palaios*, ancient, and *lithos*, a stone: *Gr.*), the implements were rudely made by a simple chipping of the stone without any attempt to make the surface even. In the later they were rubbed smooth, and these are termed *neolithic* (*neos*, new: *Gr.*). Some races have emerged from their stone age long ago, others are still living in it. When the use of bronze was discovered stone implements ceased to be made.

STREAM LINES, THEORY OF, in Shipbuilding, a new mathematical theory worked out by Mr. W. Froude, in regard to the resistance encountered by ships when moving in the water. 'The whole framework of thought by which the search for improved forms is universally directed, consists of ideas, which, if the theory of stream lines is true, are absolutely delusive and misleading.' The only causes of resistance to the motion of a ship through water are, first, surface friction, which in the case of large ships is by much the largest item; secondly, the mutual friction of the particles of water, and this is only felt when there are features sufficiently abrupt to cause eddies, so that it may be neglected in any well-designed ship; and, thirdly, wave resistance, the data for determining which, must be obtained by direct experiment with different forms to ascertain its amount for each form, the experiments being directed to discover the wave resistance of all varieties of water-line cross section, and proportion of length, breadth, and depth, so as to give comparative results of different forms, as well as the absolute results of each. 'In order to reduce wave resistance, we should make the ship very long On the other hand to reduce the surface friction, it must be made comparatively short, so as to diminish the surface of webbed skin. Thus endeavour must be made to reconcile conflicting methods of improvement; and to work out the problem in any given case, we require to know actual quantities.' As to what has been called direct head resistance, the notion is declared to be a complete delusion, for it can be shown that there is no opposing force due to the inertia of the water on the area of the ship's way. Indirectly the water causes resistance to a ship at the surface, because the pressures due to it make waves; but to a submerged body, or to the submerged portion of a ship, no resistance will be caused by the inertia of the water which is pushed aside. The theory of stream lines shows that a submerged body, if moving through a perfect fluid at uniform speed, would encounter no resistance whatever.

STRIGIL (*strigilis: Lat.*), a scraper made of horn or metal employed by bathers for removing the impurities of the skin. It is often seen in the hands of athletes in ancient works of sculpture.

SUBJECT, OBJECT, terms employed in Mental Science to denote the mind, self, or ego, and the external world or the non-ego. Thoughts and volitions, pleasures and pains, are subjective; are part of ourselves. Whatever comes to us through our senses, the impressions derived from those things that seem to be external to us, are objective.

SUDATORIUM (*Lat.*), a room in a Roman bath where the air was heated to cause perspiration.

SUFFICIENT REASON, PRINCIPLE OF. This so-called law or principle affirms that certain conditions attend every fact and event, constituting the reason why they exist or have happened. It was put forward by Leibnitz to explain moral necessity, by which he understood the mind selecting the best or following the strongest inclination.

SUFFIX (*sub*, under; *fixum*, to attach: *Lat.*), an addition to the end of a word indicating some change in the meaning. Thus, in heirship, childhood, boldness, freedom, the last syllable in each is a suffix.

SUMMUM BONUM (the highest good: *Lat.*), that the discovery and acquisition of which ought to be the great end and aim of life. Plato and Aristotle thought that the highest happiness of man was philosophy or the pursuit of truth, and that was only attainable by the practice of justice and virtue. Butler and others make virtue not happiness the highest object of man.

SUN. This splendid body having been very closely scrutinised by many observers, much new information has been gathered as to his constitution, though much still remains to be learned. It was formerly supposed that the sun's body was dark, but surrounded by a glowing atmosphere, the photosphere, and that the maculæ were cavities in that atmosphere through which the body was seen. But it is now thought that the mass of the sun is in a fluid, if not a gaseous, state, and hotter than the surrounding atmosphere. By the constant use of the spectroscope there have been detected in him the metals iron, zinc, copper, aluminium, sodium, magnesium, cobalt, nickel, calcium, chromium, titanium, and manganese, all in the gaseous condition, as well as the gases hydrogen and oxygen. The latter gas was for long unrecognised, and it is supposed to keep for the most part below the visible surface. There is also a bright line, known as No. 1474, amongst the dark lines of the preceding bodies. This bright line has been attributed to an unknown metal, for which the name of helium has been proposed, but some physicists believe it to be a line of hydrogen. It has been found that the sun's spots have a proper motion, those nearer the solar equator moving more rapidly than those which are more distant. Moreover, it has been discovered that the spots are attended with periodical changes, the cause of which is not known. These changes are believed by some to correspond with variations in magnetic declination, in auroras, in the number of cyclones, and in rainfall, and it is thought that the evidence points to a common cycle. It has even been suggested that commercial crises have relation to the sun's spot periods. With regard to the sun's envelopes we may begin with the atmosphere, which extends some 300 or 400 miles from the surface, and contains the vapourous metals already mentioned. Above this is the *Chromosphere*, or more properly *Chromatosphere*, called also the *Sierra*, with a thickness of from 6000 to 7000 miles, outside which is the *Corona*. The lower part of this is seen round the dark moon when an eclipse is total, as a ring of pearly lustre crossed by radiating lines. In this region are seen those objects of irregular form and position called flames, prominences, or protuberances, which are usually red, but sometimes yellow or violet. These are outbursts of incandescent hydrogen which reach to perhaps 100,000 miles from the sun's surface. The corona extends to about a million of miles from the sun. Its structure is complicated, and the spectroscope shows that it is only partly gaseous, the rest consisting of incandescent solid or liquid bodies. Observations at different eclipses prove that it varies greatly in extent and structure. Beyond the corona long rays have been seen extending as far as five millions of miles from the sun. But this is not all, for there is 'a softened luminosity' which has been traced to the enormous distance of ten millions of miles along the zodiac, and this is thought to be part of the zodiacal light whose mysterious nature has long puzzled astronomers. The brilliancy of the sun's light at the earth's surface is said to be equal to the light emitted by 5774 candles at the distance of 13⅓ inches. It has been computed that the heat received by the earth from the sun in the course of a year would be sufficient to melt a layer of ice spread over the earth to the thickness of 32¾ yards. The sources from which the sun's enormous heat is derived have often formed the subject of speculation. Some have thought that the heat may be caused by the impingement of meteoric bodies upon the sun. Helmholtz suggests that the heat may be produced by the contraction from cooling of the sun's mass. The influence of this great luminary upon the earth is felt in three ways: in consequence of his rotation and our rotation the magnetism of the earth and the meteorological conditions of our atmosphere are affected; then there is a cyclonic effect produced by the meteorological disturbances of his surface; and lastly, there are the effects of light and heat which are caused by the vibrations of his particles. 'It cannot be doubted,' says Dr. Balfour Stewart, 'that a great generalisation is looming in the distance, a mighty law, we cannot yet tell what, that will reach us we cannot yet say when. It will involve facts hitherto inexplicable, facts that are scarcely received as such because they appear opposed to our present knowledge of their causes.'

SUNDEW. [See DROSERA.]

SYMPIESOMETER (*sun*, with; *piezo*, I press; *metron*, a measure: *Gr.*), a peculiar form of barometer consisting of a glass tube bent into a syphon shape, and containing air as well as a non-volatile fluid, usually glycerine. The varying pressure of the atmosphere causes the fluid to rise or fall. The indications thus afforded need correction for the temperature of the air at the time and place of the observation.

SYNOPTIC GOSPELS, a name given to the three gospels of Matthew, Mark, and Luke, because they report the same events in nearly the same way, so that some critics are of the opinion that they were all based upon the same older document; whilst the fourth gospel is marked by discrepancies and the introduction of new views.

SYSTEMIC, in Medicine, what concerns the entire bodily system, not something merely local.

T

TABU, a mystical rite amongst the heathen Polynesians by which an object is rendered sacred. Death or severe punishment is the penalty for infringing tabu. The objects thus protected are usually the property of the chiefs. Captain J. E. Erskine thought, from the accounts given of its operation in the Fiji Islands, that although the services of a priest are sometimes called in to assist, tabu is in fact more a civil than a religious ceremony, and that the fear of offending the chief, who alone has the power of laying on or removing it, rather than the gods, is the cause of its rigid observance.

TACHYGRAPHY (*tachus*, quick; *graphe*, writing: *Gr.*), a method of rapid writing or shorthand.

TALOOKDHAR, the Indian name for the proprietor of a talook or district.

TANGIERINE ORANGE (Tangiers, North Africa), a small orange with an easily separated rind growing on a small-leaved low tree much cultivated on the shores of the Mediterranean. The rind has a strong but agreeable perfume, and the flesh is sweet and juicy.

TASIMETER (*tasis*, tension; *metron*, measure: *Gr.*), an instrument invented by Mr. T. A. Edison, of New York, for detecting and measuring minute variations of pressure by means of an electric current. Variously modified, it can be employed to detect extremely small differences of weight, heat, moisture, &c. It is founded upon the property which carbon, in a state of fine division, possesses of varying its resistance to the passage of electricity under very slight alterations of pressure. A button of carbon formed by compressing the black deposit of a petroleum lamp is placed in the circuit of an electric current, and is subjected to the pressure of the body whose increased or lessened weight, heat, &c., is to be measured. The greater the pressure, the less is the resistance. The variations thus produced are indicated by a galvanometer through which the current is made to pass. The apparatus thus forms a thermometer of marvellous delicacy, and the inventor believes that it will show a difference of temperature as small as the 1-50,000th of a degree Fahrenheit.

TASMANIANS, the native people of Van Diemen's Land or Tasmania, the last survivor of whom, an old woman, died in 1876. In many respects they resembled the Australians, but differed from them in having crisp, almost woolly hair in place of flowing and silky hair.

TECHNICAL EDUCATION, that instruction which should succeed the elementary teaching of the child in order to prepare him for the life of a handicraftsman. Before he applies himself to the engrossing labours of the workshop, a foundation of principle should be laid by which the practical details of his business would be more easily learned and better understood. And along with principles should be taught various useful arts, such as drawing and mental arithmetic, which would be of service to him in every part of his career. Such a technical education as is here referred to would not only render the recipient a better workman, but would make his work more pleasant and his life more enjoyable. In many Continental countries schools have been established for giving instruction, not only in the lower grade of handicrafts, such as weaving, dyeing, lace-making, watch-making, &c., but to a higher grade, such as engineering in its numerous branches. These higher grade places of instruction are known as Polytechnic Schools or Technological Institutes. One of the best of them is at Zurich, in the poor country of Switzerland, and so excellent is the instruction given here, that pupils are attracted to it from all parts of Europe. Very little has been done hitherto in this direction in the wealthy empire of Great Britain, although technical schools are nowhere more needed.

TELEOLOGY (*telos*, an end or purpose; *logos*, a discourse: *Gr.*), the doctrine of final causes, or the argument that the purposiveness of things affords proof of the existence of a Creator.

TELEPHONE (*tele*, far off; *phonos*, sound: *Gr.*), an apparatus for transmitting spoken words or other sounds to a distance. Several contrivances have been devised for this purpose, the first having been that of a German named Reuss in 1861. Of the recent inventions, that of Mr. Graham Bell may be selected for description. It consists of three parts, two of which, the transmitting instrument and the receiving instrument, are exactly alike, and each may be used successively for the two purposes. Each consists of a thin iron diaphragm, about two inches in diameter, held in a wooden ring. The intermediate portion of the apparatus is more complicated. There is, first, at the transmitting end, a bar magnet, which is adjusted so as to have one end brought very near to the iron diaphragm. To the other end of the magnet is attached a bar of soft iron. This lies in the interior of a coil of well-insulated copper wire, the two ends of which extend to the receiving instrument, wherever that may be. At the receiving end there is a precisely similar arrangement of copper wire coiled round a bar of soft iron, which is attached to a magnet, the end of the latter being brought close up to, without touching, the iron diaphragm of the receiving instrument. It is to be understood that the wire of one coil forms a closed circuit with the wire of the other. Now all being arranged, the person who desires to send a message from A to B, utters it to the transmitting instrument, the diaphragm of which at once begins to vibrate. With every vibration it is thrown into contact with the magnet, from which, by reason of its elasticity, it immediately springs back. In consequence of these makings and breakings of contact, currents of electricity are generated in the coil, and flashed along the wire from A to B, where the operation we have just described is reversed. The electrical current circulating in the coil at B has the effect of increasing the magnetism of the enclosed bar. The diaphragm is thereby alternately attracted and set free in exact correspondence with the apparatus at A. The vibrations caused by the speaker at A, in the diaphragm there, are therefore repeated in the diaphragm at B, and an ear placed at the receiving instrument will hear a repetition of the speaker's words. The hearer may now in turn reply in the same manner, when the apparatus at B becomes the transmitting, and that at A the receiving instrument. On consideration it will be seen, that in working the apparatus there are no fewer than eight transformations: (1.) the speaker's vocal chords cause the air to vibrate; (2.) the diaphragm then vibrates; (3.) the magnetism of the bar is affected; (4.) a current of electricity flows along the wire; (5.) the magnetism of the bar at the receiving end is affected; (6.) the diaphragm at that end is thrown into vibration; (7.) the air then vibrates, and lastly, (8.) the tympanum of the listener's ear must vibrate before he can receive the message. Mr. T. A. Edison has invented another form of telephone, which repeats the message much more loudly than the preceding. This latter invention, which is of more complicated construction, has been brought into use in London, where what is termed the Telephone Exchange has been established. By means of a central office an indefinite number of stations can be brought into connection one with another, and private conversation can be easily carried on by wires passing through this central office when the parties are ten or twelve miles apart.

TEPIDARIUM (*Lat.*), a tepid bathing room in a Roman bath.

TERRIER (*terra*, land: *Lat.*), a list of estates belonging to a manor, of holdings under a landlord, and other similar lists connected with land.

TESSERÆ (*Lat.*), square blocks or tablets of stone or marble for pavements, mosaic work, &c.

TETE-DE-PONT (bridge-head: *Fr.*), in the military art, the fortified post at the end of a bridge to prevent an enemy crossing it.

THAUMATURGY (*thaumatourgia*: *Gr.*), the performance of what appears miraculous; in a bad sense jugglers' tricks.

THERMÆ (*Lat.*), hot springs, or hot baths, from the Greek *thermos*, hot.

THERMO-DYNAMICS, the science connected with the conversion of heat into mechanical work, or mechanical work into heat. The leading law is, that whenever work is performed by the agency of heat, an amount of heat disappears equal to the work performed, and that whenever work is expended in generating heat, the heat so obtained is equal to the work expended. Carnot showed that it is by the transference of heat from a hotter to a colder body that mechanical work is performed.

THRIPS, the gardeners' name for a small insect that infests and injures plants under glass. It is black and shining, with large prominent eyes, and is quick in its movements. It collects in numbers on the under sides of the leaves and of which it attacks the cuticle. It ought to be carefully looked for, and destroyed as soon as it is found.

THYMOL, in Chemistry, the homologue of phenol, or carbolic acid extracted from the oil of *thyme* and some other plants. It is a crystalline, nearly colourless body, dissolving with difficulty in water but readily in alcohol. It has been found useful as a deodoriser of unhealthy wounds, being preferable under some conditions to carbolic acid.

TIDE LEVEL. The mean tide level is an imaginary point equidistant at a given locality from the high and low water marks of an entire lunation. For practical purposes it is assumed to be invariable, though there are reasons to think that there are appreciable changes during the year.

TIMBRE (*Fr.*), in Acoustics, is that peculiar character of sounds by which we distinguish for example the notes of a violin from those of a harp, or one man's voice from another's. It is independent of the loudness or pitch, and is a consequence of the harmonics which accompany the principal note.

TMESIS (a division: *Gr.*), in Latin grammar, the separation of a word into two parts and the insertion of another word between them for metrical purposes. Thus the poet Ennius wrote, 'Saxo cere — comminuit — brum,' for 'Saxo cerebrum comminuit' (He smashed his brains with a stone).

TONOMETER (*tonos*, a musical note; *metron*, a measure: *Gr.*), an apparatus for accurately measuring the number of beats per second made by a vibrating body such as a tuning fork. There are several inventions for this purpose. [See SIREN (*St.*).]

TOPE (*sthupa*, a mound or cairn: *Sans.*), a name given in India to tumuli, pillars, towers, &c., having a sacred or monumental character. They are sometimes large and elaborate architectural structures.

TORPEDO, in military affairs, an iron vessel filled with an explosive material, and used both in attack and for defence, and either on land or under water. The explosive material is usually either gun-cotton or dynamite. [See these articles.] Torpedoes are exploded by electricity or by concussion. The Whitehead torpedo is a narrow cigar-shaped weapon which is driven through the water by means of compressed air. The fish torpedo is another form which is similarly impelled but below the surface of the water. Both of these explode on striking any object. In the case of the latter, if it fails to hit it comes up to the surface, and a trigger guard renders it harmless, and at the same time enables it to be recovered.

TORQUE or **TORK** (*torques*, a twisted neck-chain: *Lat.*), an ornament for the neck worn by the ancient Britons and Gauls, consisting of a chain composed of interlaced rings. Titus Manlius, a hero of ancient Rome, acquired the surname of Torquatus from having taken the *torques* from the neck of a Gaul whom he had slain in battle. Torques are sometimes coiled in a spiral, and then they are really armlets, like the bronze elastic armlets found in Italy.

TOTEM WORSHIP, the worship by a clan of uncivilised people of some particular animal or vegetable from which the clan takes a surname.

TRACHEÆ (*Lat.*), the tubes which penetrate through every part of the bodies of insects by means of continual ramifications for the purpose of aërating the blood. They commence at the external openings called spiracles which are furnished with a kind of sieve very variously formed which prevents the entrance of dust.

TRADE WINDS. [See p. 760.] The anti-trade winds are a consequence of the trades, for the heated equatorial air at first flowing upwards again reaches the surface of the earth at about 30° north and south, and then partly returns to the equator and partly makes its way towards the poles as a south-west wind in the northern, and as a north-west in the southern hemisphere.

TRICHINIASIS or **TRICHINOSIS**, a disease arising from the presence of the microscopic worm called *Trichina spiralis*, which taken into the body with the flesh of a trichina-infested animal rapidly spreads into the whole muscular system. The pig is apt to be troubled with this disease, and hence the danger of eating pork not thoroughly cooked. The disease in man is sometimes epidemic.

U

UGRIO-FINNIC TONGUES, a division of the ALTAIC (*St.*) languages spoken in Eastern Europe and Northern Asia, and comprising the Finn, Lapp, Magyar, and other dialects

UHLANS, German cavalry, armed with the lance, sabre, and carbine.

UNION JACK, the national flag of the United Kingdom. It consists of a combination of the red cross of St George on a white ground for England, the white saltire or cross of St. Andrew on a blue ground for Scotland, and the red cross of St. Patrick on a white ground for Ireland

URTICATING ORGANS (*urtica*, a nettle: *Lat.*), organs for stinging possessed by many water animals of low type. For example, in the tentacles of the sea anemones there are lodged numerous minute capsules, each containing a coiled-up thread carrying at its tip a spiculum This can be darted forth at the will of the animal; and it is supposed that its prey is thus attacked and rendered helpless.

UTRICLE, PRIMORDIAL (*utriculus*, a skin bottle: *Lat*), in Botany, the membrane which lines the inside of a vegetable cell. The external coat of the cell is composed of a non-azotised substance called CELLULOSE. Inside there is at first a mucilaginous azotised matter called PROTOPLASM (*St*), which in the progress of growth forms a layer on the inner wall of the cell. This is the primordial utricle. As the process of lignification advances, the utricle disappears in consequence of its becoming incorporated with the cell wall

V

VALI or **WALI**, the governor of a vilayet or province in Turkey.

VENUS' FLY-TRAP, a North American bog plant, the *Dionæa muscipula* of botanists, nat. order *Droseraceæ*. It is one of the so-called CARNIVOROUS PLANTS (*St.*). The leaves are composed of two lobes with long hairs at their edges. There are some irritable bristle-like hairs on their surfaces, which secrete a fluid which forms a bait for insects. When an insect touches these hairs, the lobes move upwards and the interlocking hairs hold it fast until it dies.

VERA CAUSA (*Lat.*), a phrase applied in reasoning as to the explanation of a given phenomenon to any suggested cause which is recognised as having a real existence in nature, and is not a mere hypothesis or figment of the mind.

VERST, a Russian measure of length equal to 0 621 of a British statute mile (about 3500 feet), and 0·937 of a kilometre.

VESICA (a bladder: *Lat.*), in Mediæval Art, the oval frame or glory pointed at each end, which surrounded the figure of Christ in painted windows, &c. It is conjectured to represent a fish with reference to the Greek word *ichthus* (a fish), an anagram made of the first letters of the words signifying Jesus, Christ, Son, God, Saviour (*Jesos, Christos, uios, theos, soter*).

VIKINGS, the piratical Northmen or Normans who ravaged the coasts of Europe, from the ninth to the eleventh centuries. Some say that the word signifies warriors; others that it is derived from *vic*, a bay, the lurking-place of the robbers.

VINEGAR PLANT, a fungus which has the property of setting up the acetic fermentation in a solution of sugar, and converting it into vinegar, if a small piece of the plant be placed therein. It has received a distinct name from botanists (*Mycoderma aceti*), but it is said to be really the vegetative form of the common blue mould *Penicillium glaucum*, which is thought to be the reproductive form of the same vegetable.

VISCOSITY (*viscosus*, viscous: *Lat.*), a term to express a less degree of mobility in the molecules of bodies than that possessed by fluids such as water. Treacle and liquid-glue are viscous bodies.

VIS VIVA (living force: *Lat.*), in Mechanics, is the mechanical effect of a moving body and is ascertained numerically by multiplying the mass of the body by the square of the velocity.

VOCAL CHORDS, two vibratile chords at the sides of the glottis, a slit-shaped opening in the LARYNX of mammals. The air striking against these bodies when in a state of vibration is the cause of vocal sounds, whether the roar of a lion, the bark of a dog, or the speech of man. All the charms of a singer's voice depend upon these chords. Reptiles have no vocal chords, and consequently they can only hiss.

VULCANITE. [See CAOUTCHOUC.]

W

WAX, MINERAL, a fossil hydrocarbon of a brownish colour, found in bituminous shale in Moldavia. It is allied to PARAFFIN, and has been named *ozokerite* by mineralogists. An extensive bed of a somewhat similar substance, but of a black colour, has been found in Utah, U.S., America. This has been called *zietriskisite*.

WAX, VEGETABLE. Wax is yielded by some palm trees and some plants belonging to the *Myricaceæ, Artocarpaceæ, Terebinthaceæ*, and *Cucurbitaceæ*. The palm wax of the Andes exudes from the trunk of a New Granada palm (*Ceroxylon andicolum*), and forms an article of commerce. A Brazilian palm (*Copernicia cerifera*) affords the Carnauba wax, which is found coating the leaves with white scales. Several species of *Myrica*, growing in North America, Africa, and China, yield wax. Japan wax is the produce of the fruit of the *Rhus succedanea*, a small cultivated tree, and is exported in hard, white blocks. The Japanese make candles of it. The surface of the fruit of the White Gourd (*Benincasa cerifera*) is covered with a secretion known as Petha wax in India.

WEIGHTS AND MEASURES. An Act of Parliament was passed in 1878 (41 & 42 Vict., ch. 49) for the purpose of enforcing uniformity in weights and measures throughout the United Kingdom, and imposing a fine on every person who uses, or has in his possession for use, for trade a weight or measure which is not of the denomination of some Board of Trade standard. All trade contracts and dealings are to be in terms of Imperial Weights and Measures defined in the Act, and all local or customary measures and the use of heaped measures have ceased to be lawful. Exceptions are, however, made from the rule of avoirdupois weight, in the case of gold, silver, platinum, diamonds, and other precious stones. Moreover, the old weights and measures employed by apothecaries remain untouched by the Act. The bronze bar and platinum weight held by the Board of Trade in the Standards department continue to be the Imperial Standards of measures and weights, and the four copies, one at the Mint, a second in the possession of the Royal Society, a third deposited at the Royal Observatory, Greenwich, and a fourth lodged at the Royal Palace, Westminster, are to be deemed Parliamentary Standards.

WELWITSCHIA MIRABILIS, one of the most singular members of the vegetable kingdom, inasmuch as it only puts forth its two cotyledonary leaves, a striking case of arrested development. This uncouth plant belongs to the nat.

order *Gnetaceæ*, and is a native of west tropical Africa, to the south of the equator, where it was discovered by Dr. Welwitsch. It has a rough stem, never exceeding a foot in height, but varying according to age, from a few inches to five or six feet, at the top of which its inconspicuous flowers are annually put forth on small branches.

WINE. The average yearly production of wine in European countries has been estimated to amount to the following quantities (in gallons):—

France	1,225,090,000
Spain	442,000,000
Portugal	110,500,000
Italy	693,003,000
Austria-Hungary	498,300,000
Germany	143,060,000
Switzerland	19,800,000
Russia and European Turkey	47,000,000
Greece and Cyprus	25,000,000
Roumania	14,680,000

WINTER'S BARK, the bark of a tree growing in South America, the *Drimys Winteri*, nat. order *Magnoliaceæ*. The bark was first brought to England in 1579, from the Straits of Magellan, by Captain Winter. It is or was employed in medicine as an aromatic stimulant.

WOMBAT, or Ursine Opossum, one of the pouched animals of Australia. There are three species, two of which are placed in the genus *Phascolomys*. The best known resembles a small bear in general appearance, and is about the size of a badger. It lives in the mountain near Port Jackson, and only issues from its burrow at night.

WORK, MECHANICAL, is exhibited by the displacement of a body by means of force, and is represented numerically by multiplying the force by the displacement it produces in its point of application. The FOOT-POUND (*St.*) is taken as the unit of work

Y

YATAGHAN (*Turkish*), a curved flat sword without a guard, used by the Albanians and Montenegrins. A dagger-shaped two-edged sword of this name was formerly carried by the Janizaries.

Z

ZERO, ABSOLUTE, in Thermometry. It has been found by experiment that atmospheric air, at constant pressure, expands 1-491 of its volume for each degree of Fahrenheit (1-273 for each degree Centigrade). Consequently, if the temperature of a given mass of air at 32° F. (or 0° C.) could be lowered to –459° F. (or –273° C.), the given mass of air would be reduced to a mathematical point. This temperature has received the name of the absolute zero of temperature, and when other temperatures are reckoned from it, they are termed absolute temperatures.

ZITHER, (*cithara: Lat.*), a musical instrument, something like a guitar, with from twenty to thirty strings, and from four to six wires, on which the melody is played by the finger, whilst the others serve for an accompaniment played by the other hand. It had its origin in the Bavarian Highlands.

ZOOLOGICAL GEOGRAPHY, the study of the distribution of animals over the globe and of the causes of that distribution. Such study involves inquiries, not only as to the range in space of the different existing species of animals, but also as to the information afforded by the fossil remains of animals inhabiting a region at an epoch immediately preceding the present—as to the conditions and changes of the earth's surface so far as they bear upon the question of animal distribution—as to the means of dispersal and migration of animals, &c. Much light has been thrown upon the subject by the doctrine of evolution, which has at the same time stimulated and assisted inquiry. Dr. Sclater has mapped out the world into seven great regions, confining himself to mammals, birds, reptiles, batrachians, and fishes dwelling in lakes and rivers:—1. Palæarctic Region. 2. Ethiopian Region. 2*a*. Lemurian Sub-region.

3. Indian Region. 4. Nearctic Region—Arctogæa. 5. Neotropical Region. 5a. Antillean Sub-region—Dendrogæa. 6. Australian Region—Antarctogæa. 7. Pacific Region—Ornithogæa. He has subdivided these regions into several sub-regions. Thus, the Palæarctic Region is portioned into seven:—1. The Cis-Atlantean Sub-region, embracing all that part of the Palæarctic Region lying south of the Mediterranean Sea. 1a. The Atlantic Islands. 2. The European Sub-region. 3. The Siberian Sub-region, embracing the whole of Northern Asia. 4. The Mantchurian Sub-region, containing Northern China and the adjoining part of Mongolia. 5. The Japanese Sub-region, embracing the Japanese Islands. 6. The Tartarian Sub-region, containing the great desert region of Central Asia. 7. The Persian Sub-region, embracing Persia, Asia Minor, and Syria. The Ethiopian Region is divided into:—1. Western Africa, from the Senegal to the Congo. 2. South-Western Africa, or Angola and Benguela. 3. South Africa. 4. South-Eastern Africa, from the Portuguese possessions to the Somali coast. 5. North-Eastern Africa, including Abyssinia, Nubia, and Egypt. 6. Arabia. The Indian Region is subdivided into:—1. British India. 2. Central and Southern China. 3. Burmah, Siam, and Cochin-China. 4. The Malay Peninsula. 4a. Andaman and Nicobar Islands. 5. East Indian Islands. 6. Philippine Archipelago. The Neotropical Region, the richest in animal life of any of the principal divisions of the globe, is portioned into:—1. Central American Sub-region, from Southern Mexico to Panama. 2. Andean or Columbian Sub-region. 3. Amazonian Sub-region, embracing the watershed of the Orinoco and Amazons, up to the hills and including the highlands of Guiana. 4. The South Brazilian Sub-region. 5. The Patagonian Sub-region 6. The Galapagos. Of the Australian Region, the subdivisions are:—1. Australia and Tasmania. 2. Papua and the Papuan Islands. 3. The Solomon Islands. In the Pacific Region, where there are no mammals except bats, birds being the chief form of vertebrate life, there are only three subdivisions:—1. New Zealand. 2. Polynesia. 3. The Sandwich Islands. On this subject, Mr. A. R. Wallace's work on 'The Geographical Distribution of Animals' should be consulted. 'There is nothing,' he says, 'that the study of geology teaches us that is more certain or more impressive than the extreme instability of the earth's surface. Everywhere beneath our feet we find proofs that what is land has been sea, and where oceans now spread has once been land; and that this change from sea to land and from land to sea has taken place not once or twice only, but again and again during countless ages of past time. Now the study of the distribution of animal life upon the present surface of the earth causes us to look upon this constant interchange of land and sea, and this making and unmaking of continents, this elevation and disappearance of islands, as a potent reality, which has always and everywhere been in progress, and has been the main agent in determining the manner in which living things are now grouped and scattered over the earth's surface.'

ZOOSPORES (*zoos*, living; *spora*, seed: *Gr.*), minute bodies which issue from the cells of many species of ALGÆ without any previous process of fertilisation, and after moving awhile through the water by means of ciliæ, settle down to germinate and produce a form resembling the parent plant. The difference between a zoospore and a spermatozoid is that the former, when separated from the parent, becomes encysted and at once developed into a new individual.

ZOUAVES, originally the name of the warlike inhabitants of Zuaua in Algeria; then the bodyguards of the Beys; lastly, French infantry troops, dressed in the Turkish fashion, with turbans, loose jackets, and baggy trousers. The native Algerian troops, in similar uniform, are styled Turcos.

PRINTED BY BALLANTYNE, HANSON AND CO
EDINBURGH AND LONDON.
